#### Abstract

A $(k, \delta, \varepsilon)$-locally decodable code $C: \mathbf{F}_{q}^{n} \rightarrow \mathbf{F}_{q}^{N}$ is an error-correcting code that encodes each message $\vec{x}=\left(x_{1}, x_{2}, \ldots, x_{n}\right) \in \mathbf{F}_{q}^{n}$ to a codeword $C(\vec{x}) \in \mathbf{F}_{q}^{N}$ and has the following property: For any $\vec{y} \in \mathbf{F}_{q}^{N}$ such that $d(\vec{y}, C(\vec{x})) \leq \delta N$ and each $1 \leq i \leq n$, the symbol $x_{i}$ of $\vec{x}$ can be recovered with probability at least $1-\varepsilon$ by a randomized decoding algorithm looking only at $k$ coordinates of $\vec{y}$. The efficiency of a $(k, \delta, \varepsilon)$-locally decodable code $C: \mathbf{F}_{q}^{n} \rightarrow \mathbf{F}_{q}^{N}$ is measured by the code length $N$ and the number $k$ of queries. For any $k$-query locally decodable code $C: \mathbf{F}_{q}^{n} \rightarrow \mathbf{F}_{q}^{N}$, the code length $N$ is conjectured to be exponential of $n$, i.e., $N=\exp \left(n^{\Omega(1)}\right)$, however, this was disproved. Yekhanin [In Proc. of STOC, 2007] showed that there exists a 3-query locally decodable code $C: \mathbf{F}_{2}^{n} \rightarrow \mathbf{F}_{2}^{N}$ such that $N=\exp \left(n^{(1 / \log \log n)}\right)$ assuming that the number of Mersenne primes is infinite. For a 3 -query locally decodable code $C: \mathbf{F}_{q}^{n} \rightarrow \mathbf{F}_{q}^{N}$, Efremenko [ECCC Report No.69, 2008] reduced the code length further to $N=\exp \left(n^{O\left((\log \log n / \log n)^{1 / 2}\right)}\right)$, and also showed that for any integer $r>1$, there exists a $k$-query locally decodable code $C: \mathbf{F}_{q}^{n} \rightarrow \mathbf{F}_{q}^{N}$ such that $k \leq 2^{r}$ and $N=\exp \left(n^{O\left((\log \log n / \log n)^{1-1 / r}\right)}\right)$. In this paper, we present a query-efficient locally decodable code by introducing a technique of "composition of locally decodable codes," and show that for any integer $r>1$, there exists a $k$-query locally decodable code $C: \mathbf{F}_{q}^{n} \rightarrow \mathbf{F}_{q}^{N}$ such that $k \leq 3 \cdot 2^{r-2}$ and $N=\exp \left(n^{O\left((\log \log n / \log n)^{1-1 / r}\right)}\right)$. Keywords: Locally Decodable Codes, $S$-Matching Vectors, $S$-Decoding Polynomials, Composition of Locally Decodable Codes, Perfectly Smooth Decoders, Private Information Retrieval.

## 1 Introduction

Conventional error-correcting codes $C: \mathbf{F}_{q}^{n} \rightarrow \mathbf{F}_{q}^{N}$ allow one to encode any $\vec{x}=\left(x_{1}, x_{2}, \ldots, x_{n}\right) \in \mathbf{F}_{q}^{n}$ to $C(\vec{x}) \in \mathbf{F}_{q}^{N}$ and have the following property: For any $\vec{y} \in \mathbf{F}_{q}^{N}$ such that $d(\vec{y}, C(\vec{x})) \leq \delta N$, the original message $\vec{x}$ can be recovered by looking at entire coordinates of $\vec{y}$. If one is interested in recovering a single symbol $x_{i}$ of $\vec{x}$, more efficient schemes are possible. Such schemes are known as locally decodable codes $C: \mathbf{F}_{q}^{n} \rightarrow \mathbf{F}_{q}^{N}$ that allow recovery of any single symbol $x_{i}$ of $\vec{x} \in \mathbf{F}_{q}^{n}$ by looking only at $k$ randomly chosen coordinates of $\vec{y} \in \mathbf{F}_{q}^{N}$ such that $d(\vec{y}, C(\vec{x})) \leq \delta N$. Informally, a $(k, \delta, \varepsilon)$-locally decodable code $C: \mathbf{F}_{q}^{n} \rightarrow \mathbf{F}_{q}^{N}$ is an error-correcting code that encodes each message $\vec{x}=\left(x_{1}, x_{2}, \ldots, x_{n}\right) \in$ $\mathbf{F}_{q}^{n}$ to a codeword $C(\vec{x}) \in \mathbf{F}_{q}^{N}$ and has the following property: For any $\vec{y} \in \mathbf{F}_{q}^{N}$ such that $d(\vec{y}, C(\vec{x})) \leq$ $\delta N$ and each $1 \leq i \leq n$, the symbol $x_{i}$ of $\vec{x}$ can be recovered with probability at least $1-\varepsilon$ by a randomized decoding algorithm looking only at $k$ coordinates of $\vec{y}$.

### 1.1 Known Results

From theoretical and practical point of view, we are interested in designing a $(k, \delta, \varepsilon)$-locally decodable code $C: \mathbf{F}_{q}^{n} \rightarrow \mathbf{F}_{q}^{N}$ as shorter $N$ as possible and as smaller $k$ as possible. The notion of locally de-
codable codes was considered in several contexts [2, 20, 18], and Katz and Trevisan [16] were the first to provide a formal definition of locally decodable codes and prove lower bounds for the code length. Gasarch [8] and Goldreich [10] conjectured that for a $k$-query locally decodable code $C: \mathbf{F}_{q}^{n} \rightarrow \mathbf{F}_{q}^{N}$ with $k>1$, the code length $N$ is unavoidable to be the exponential of $n$, i.e., $N=\exp \left(n^{\Omega(1)}\right)$. In Table 1, we summarize the known results on the code length for $k$-query locally decodable codes.

Table 1: Known Results on the Code Length

|  | Upper Bound | Lower Bound |  |  |
| :---: | :---: | :---: | :---: | :--- |
| 2-Query | $\exp (O(n))$ | $[15]$ | $\exp (\Omega(n))$ | [15] |
| 3-Query | $\exp \left(n^{1 / 2}\right)$ | $[4]$ | $\tilde{\Omega}\left(n^{2}\right)$ | [15, 23] |
| $k$-Query | $\exp \left(n^{O(\log \log k) / k \log k}\right)$ | $[5]$ | $\tilde{\Omega}\left(n^{1+1([k / 2\rceil-1)}\right)$ | [15, 23] |

Yekhanin [25, 26] improved the upper bound for the code length of 3-query locally decodable codes to $N=\exp \left(n^{1 / 32582657}\right)$ and disproved the conjecture [8, 10] on the code length of 3-query locally decodable codes, i.e., if there exist infinitely many Mersenne primes, then $N=\exp \left(n^{O(1 / \log \log n)}\right)$ for infinitely many $n$ 's. Very recently, Efremenko [7, Theorem 3.8] improved much further the upper bound for the code length of 3 -query locally decodable codes to

$$
N=\exp (\exp (O(\sqrt{\log n \cdot \log \log n})))=\exp \left(n^{O\left((\log \log n / \log n)^{1 / 2}\right)}\right)
$$

by introducing the notions of $S$-matching vectors [7, Definition 3.1] and $S$-decoding polynomials [7, Definition 3.4] - this reduces the code length of 3-query locally decodable codes and removes the unproven assumption that infinitely many Mersenne primes exist. For any $k>2$, Efremenko [7, Theorem 3.6] also disproved the conjecture [8, 10] on the code length of $k$-query locally decodable codes, and showed that for any $r>1$, there exists a $k$-query locally decodable code such that $k \leq 2^{r}$ and

$$
N=\exp \left(\exp \left(O\left(\sqrt[r]{\log n \cdot(\log \log n)^{r-1}}\right)\right)\right)=\exp \left(n^{O\left((\log \log n / \log n)^{1-1 / r}\right)}\right)
$$

### 1.2 Main Result

In this paper, we present an improved construction of a $k$-query locally decodable code $C: \mathbf{F}_{q}^{n} \rightarrow \mathbf{F}_{q}^{N}$, and show that for any $r>1$, there exists a $k$-query locally decodable code such that $k \leq 3 \cdot 2^{r-2}$ and

$$
N=\exp \left(\exp \left(O\left(\sqrt[r]{\log n \cdot(\log \log n)^{r-1}}\right)\right)\right)=\exp \left(n^{O\left((\log \log n / \log n)^{1-1 / r}\right)}\right) .
$$

Our construction of the $3 \cdot 2^{r-2}$-query locally decodable codes is partially based on the construction by Efremenko [7. To reduce the number of queries, we introduce a technique of "composition of locally decodable codes." In fact, we show that for a $k_{1}$-query locally decodable code and a $k_{2}$-query locally decodable code, there exists a $k_{1} k_{2}$-query locally decodable code. Applying our technique of "composition of locally decodable codes" to the 3-query locally decodable code [7, Theorem 3.8] and the $2^{r-2}$ query locally decodable code [7, Theorem 3.6], a $3 \cdot 2^{r-2}$-query locally decodable code is achieved.

### 1.3 Application of Locally Decodable Codes

Locally decodable codes have many applications in complexity theory and cryptography (see, e.g., [21, 8]). In particular, locally decodable codes are closely related to designing efficient private information retrieval. Informally, a $k$-server private information retrieval is a protocol that consists of a user $\mathcal{U}$ and $k$ databases $\mathcal{D} \mathcal{B}_{1}, \mathcal{D} \mathcal{B}_{2}, \ldots, \mathcal{D} \mathcal{B}_{k}$ with identical data $\vec{x}=\left(x_{1}, x_{2}, \ldots, x_{n}\right)$, where each database $\mathcal{D} \mathcal{B}_{j}$ does not communicate to any other database $\mathcal{D} \mathcal{B}_{h}$, and allows the user $\mathcal{U}$ to retrieve $x_{i}$ of $\vec{x}$ while any of the $k$ databases $\mathcal{D B}_{1}, \mathcal{D B}_{2}, \ldots, \mathcal{D B}_{k}$ learns nothing about $i$. Private information retrieval was introduced by Chor et al. [6], and the efficiency of a $k$-server private information retrieval is measured by its communication complexity $C_{k}(n)$, i.e., the total amount of bits exchanged between the user $\mathcal{U}$ and each of the $k$ databases $\mathcal{D}_{1}, \mathcal{D}_{2}, \ldots, \mathcal{D}_{k}$. For further details on $k$-server private information retrieval, see, e.g., [1, 17, 13, 14, 11, 15, 4, 3, 19, 24].

Table 2: Known Results on the Communication Complexity

|  | Upper Bound |  | Lower Bound |  |
| :---: | :---: | :--- | :---: | :---: |
| 1-Server | $n+1$ | $[6]$ | $n$ | $[6]$ |
| 2-Server | $n^{1 / 3}$ | $[6, ~[12]$ | $5 \log n$ | $[22]$ |
| 3 -Server | $n^{O\left((\log \log n / \log n)^{1 / 2}\right)}$ | $[7]$ | - |  |
| 4-Server | $n^{1 / 7.87}$ | $[5]$ | - |  |
| $k$-Server | $n^{O(\log \log k / k \log k)}$ | $[5]$ | - |  |

In Table 2, we summarize the known results on the communication complexity $C_{k}(n)$ for $k$-server private information retrieval. In particular, Efremenko [7, Theorem 3.6] showed that a communica-tion-efficient $k$-server private information retrieval exists for a specific $k>1$, i.e., for any $r>1$, there exists a $k$-server private information retrieval such that $k \leq 2^{r}$ and $C_{k}(n)=n^{O\left((\log \log n / \log n)^{(r-1) / r}\right)}$.

## 2 Preliminaries

### 2.1 Locally Decodable Codes

We use $\mathbf{F}_{q}$ to denote a finite field of $q$ elements and $d(\vec{x}, \vec{y})$ to denote the Hamming distance of vectors $\vec{x}=\left(x_{1}, x_{2}, \ldots, x_{n}\right) \in \mathbf{F}_{q}^{n}$ and $\vec{y}=\left(y_{1}, y_{2}, \ldots, y_{n}\right) \in \mathbf{F}_{q}^{n}$, i.e., the number of indices such that $x_{i} \neq y_{i}$. For any integer $a<b$, we use $[a, b]$ to denote the set $\{a, a+1, \ldots, b\}$. For any integer $m>1$, let $\mathbf{Z}_{m}=$ $\{0,1, \ldots, m-1\}$ and $\mathbf{Z}_{m}^{*}=\left\{z \in \mathbf{Z}_{m}: \operatorname{gcd}(z, m)=1\right\}$.
Definition 2.1 ([16]) We say that $C: \mathbf{F}_{q}^{n} \rightarrow \mathbf{F}_{q}^{N}$ is a $(k, \delta, \varepsilon)$-locally decodable code if for each $i \in$ $[1, n]$, there exists a randomized decoding algorithm $D_{i}: \mathbf{F}_{q}^{N} \rightarrow \mathbf{F}_{q}$ such that (1) for any message $\vec{x}=$ $\left(x_{1}, x_{2}, \ldots, x_{n}\right) \in \mathbf{F}_{q}^{n}$ and any $\vec{y} \in \mathbf{F}_{q}^{N}$ such that $d(C(\vec{x}), \vec{y}) \leq \delta N, \operatorname{Pr}\left[D_{i}(\vec{y})=x_{i}\right] \geq 1-\epsilon$; (2) the algorithm $D_{i}$ makes at most $k$ queries to $\vec{y}$.

We say that a $(k, \delta, \epsilon)$-locally decodable code $C$ is linear if $C$ is linear over $\mathbf{F}_{q}$ and is nonadaptive if for each $i \in[1, n]$, the decoding algorithm $D_{i}$ makes all its queries simultaneously. In this paper, we deal with only linear and nonadaptive ( $k, \delta, \epsilon$ )-locally decodable codes.

Definition $2.2([21])$ We say that $C: \mathbf{F}_{q}^{n} \rightarrow \mathbf{F}_{q}^{N}$ has a perfectly smooth decoder $\mathcal{D}=\left\{D_{i}\right\}_{i \in[1 . n]}$ if for each $\vec{x} \in \mathrm{~F}_{q}^{n}$ and each $i \in[1, n], \operatorname{Pr}\left[D_{i}(C(\vec{x}))=x_{i}\right]=1$, and each query made by the randomized decoding algorithm $D_{i}$ is uniformly distributed over $[1, N]$.

Trevisan [21] observed that for a code $C: \mathbf{F}_{q}^{n} \rightarrow \mathbf{F}_{q}^{N}$, if $C$ has a perfectly smooth decoder and makes at most $k$ queries, then $C$ is a $(k, \delta, k \delta)$-locally decodable code. Thus in the rest of this paper, we use $k$-query locally decodable codes instead of $(k, \delta, \varepsilon)$-locally decodable codes.

## $2.2 \quad S$-Matching Vectors

Let $m>1$ and $h>0$ be integersDFor any $\vec{x}=\left(x_{1}, x_{2}, \ldots, x_{h}\right) \in \mathbf{Z}_{m}^{h}$ and $\vec{y}=\left(y_{1}, y_{2}, \ldots, y_{h}\right) \in \mathbf{Z}_{m}^{h}$, we use $\langle\vec{x}, \vec{y}\rangle_{m}$ to denote the inner product of $\vec{x}$ and $\vec{y}$ modulo $m$, i.e.,

$$
\langle\vec{x}, \vec{y}\rangle_{m} \equiv \sum_{j=1}^{h} x_{j} y_{j}(\bmod m)
$$

Definition $2.3([7])$ Let $S \subseteq \mathbf{Z}_{m} \backslash\{0\}$ and $\mathcal{U}=\left\{\vec{u}_{1}, \vec{u}_{2}, \ldots, \vec{u}_{n}\right\}$ be a family of vectors, where $\vec{u}_{i} \in$ $\mathbf{Z}_{m}^{h}$ for each $i \in[1, n]$. We say that a family $\mathcal{U}=\left\{\vec{u}_{1}, \vec{u}_{2}, \ldots, \vec{u}_{n}\right\}$ of vectors is $S$-matching if (1) for each $i \in[1, n],\left\langle\vec{u}_{i}, \vec{u}_{i}\right\rangle_{m}=0$; (2) for each $i, j \in[1, n]$ such that $i \neq j,\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m} \in S$.

Let $m=p_{1}^{e_{1}} p_{2}^{e_{2}} \cdots p_{r}^{e_{r}}$ be a product of $r>1$ distinct primes. Define $S_{m} \subseteq \mathbf{Z}_{m} \backslash\{0\}$ as follows: For each $s \in \mathbf{Z}_{m} \backslash\{0\}$, if either $s \equiv 0\left(\bmod p_{i}^{e_{i}}\right)$ or $s \equiv 1\left(\bmod p_{i}^{e_{i}}\right)$ for each $i \in[r]$, then $s \in S_{m}$. We refer to $S_{m}$ as the canonical set of the integer $m=p_{1}^{e_{1}} p_{2}^{e_{2}} \cdots p_{r}^{e_{r}}$.

For each integer $t \in\left[0,2^{r}-1\right]$, we use $\operatorname{bin}(t)=\left(t_{r-1}, t_{r-2}, \ldots, t_{0}\right) \in\{0,1\}^{r}$ to denote the binary representation of $t$, i.e., $t=t_{r-1} \cdot 2^{r-1}+t_{r-2} \cdot 2^{r-2}+\cdots+t_{0} \cdot 2^{0}$, and let $s_{t} \in[0, m-1]$ be an integer such that $s_{t} \equiv t_{i-1}\left(\bmod p_{i}^{e_{i}}\right)$ for each $i \in[1, r]$. Thus from the definition of $S_{m} \subseteq Z_{m} \backslash\{0\}$, it follows that $S_{m}=\left\{s_{1}, s_{2} \ldots, s_{2^{r}-1}\right\}$, where $s_{0}=0$ and $s_{2^{r}-1}=1$.

Lemma 2.1 ([9, Theorems 1.2 and 1.3]) Let $m=p_{1}^{e_{1}} p_{2}^{e_{2}} \cdots p_{r}^{e_{r}}$ be a product of $r>1$ distinct primes. Then there exists a constant $c=c(m)>0$ such that for every integer $h>0$, there exists an explicitly constructible uniform set-system $\mathcal{H}$ over the universe $[1, h]$ that satisfies the following:
(1) $|\mathcal{H}| \geq \exp \left(c \frac{\left(\log h h^{r}\right.}{(\log \log h)^{r-1}}\right)$;
(2) for each $H \in \mathcal{H},|H| \equiv 0(\bmod m)$;
(3) for any $G, H \in \mathcal{H}$ such that $G \neq H$, there exists $i \in\left[1,2^{r}-1\right]$ such that $|G \cap H| \equiv s_{i}(\bmod m)$, where $S_{m}=\left\{s_{1}, s_{2}, \ldots, s_{2^{r}-1}\right\}$ is the canonical set of $m$.

For each $H_{i} \in \mathcal{H}$, let $\vec{u}_{i}=\left(u_{i 1}, u_{i 2}, \ldots, u_{i h}\right) \in\{0,1\}^{h}$ be the incidence vector of $H_{i}$, i.e., for each $j \in$ [1, h], $u_{i j}=1$ iff $j \in H_{i}$. By Lemma [2.1, Efremenko [7] showed the following results:

Lemma 2.2 ([7, Corollary 3.3]) Let $m=p_{1}^{e_{1}} p_{2}^{e_{2}} \cdots p_{r}^{e_{r}}$ be a product of $r>1$ distinct primes and $S_{m}$ be the canonical set of $m$. Then for any integer $h>0$, there exists a family $\mathcal{U}=$ $\left\{\vec{u}_{1}, \vec{u}_{2}, \ldots, \vec{u}_{n}\right\}$ of $S_{m}$-matching vectors such that $\vec{u}_{i} \in\{0,1\}^{h} \subseteq \mathbf{Z}_{m}^{h}$ for each $i \in[n]$ and $n \geq$ $\exp \left(c \frac{(\log h)^{r}}{(\log \log h)^{r-1}}\right)$.

## $2.3 \quad S$-Decoding Polynomials

To construct a $(k, \delta, \epsilon)$-locally decodable codes of short length, the following lemma is useful.
Lemma 2.3 ([7, Fact 2.4]) For any odd integer $m>1$, there exist a finite field $\mathbf{F}_{2^{t}}$ with $t \in$ $[1, m-1]$ and an element $\gamma \in \mathbf{F}_{2^{t}}$ of order $m$, i.e., $\gamma^{m}=1$ and $\gamma^{i} \neq 1$ for each $i \in[1, m-1]$.

Let $m=p_{1}^{e_{1}} p_{2}^{e_{2}} \cdots p_{r}^{e_{r}}$ be a product of $r>1$ distinct odd primes and $\gamma \in \mathbf{F}_{2^{t}}$ be an element given by Lemma [2.3. Efremenko [7] introduced a notion of $S$-decoding polynomials, which plays a crucial role to construct a query-efficient locally decodable code.

Definition 2.4 ([7, Definition 3.4]) For any $S \subseteq \mathbf{Z}_{m} \backslash\{0\}$, we say that $P(x) \in \mathbf{F}_{2^{t}}[x]$ is an $S$ decoding polynomial if (1) $P\left(\gamma^{s}\right)=0$ for each $s \in S$; (2) $P\left(\gamma^{0}\right)=P(1)=1$.

Efremenko [7] showed that there exists an $S$-decoding polynomial with a few monomials.
Lemma 2.4 ([7, Claim 3.1]) For any odd integer $m=p_{1}^{e_{1}} p_{2}^{e_{2}} \cdots p_{r}^{r_{r}}$ with $r>1$ and any $S \subseteq$ $\mathbf{Z}_{m} \backslash\{0\}$, there exists an $S$-decoding polynomial $P(x)$ with at most $|S|+1$ monomials.

Remark 2.1 The number of monomials of an $S$-decoding polynomial is closely related to the number of queries of the corresponding locally decodable code. In fact, the number of monomials of an $S$ decoding polynomial is $k$ iff the number of queries of the corresponding locally decodable code is $k$.

Let $m=p_{1}^{e_{1}} p_{2}^{e_{2}} \cdots p_{r}^{e_{r}}$ be a product of $r>1$ distinct odd primes. It is immediate that $\left|S_{m}\right|=2^{r}-1$ from the definition of the canonical set $S_{m}$ of $m$. Thus from Lemma 2.4, we have the following lemma:

Lemma 2.5 ([7]) Let $m=p_{1}^{e_{1}} p_{2}^{e_{2}} \cdots p_{r}^{e_{r}}$ be a product of $r>1$ distinct odd primes. Then there exists an $S_{m}$-decoding polynomial $P(x)$ with at most $2^{r}$ monomials.

## 3 Known Construction for $\boldsymbol{k}$-Locally Decodable Codes

We describe the construction of $(k, \delta, \varepsilon)$-locally decodable codes given by Efremenko [7].

### 3.1 Encoding

Let $m=p_{1}^{e_{1}} p_{2}^{e_{2}} \cdots p_{r}^{e_{r}}$ be a product of $r>1$ distinct odd primes, $\gamma \in \mathbf{F}_{2^{t}}$ be an element determined by Lemma 2.3, and $P(x)=a_{0}+a_{1} x^{b_{1}}+\cdots+a_{k-1} x^{b_{k-1}} \in \mathbf{F}_{2^{t}}[x]$ be an $S_{m}$-decoding polynomial, where $S_{m}$ is the canonical set of $m$. For each $i \in[1, n]$, let $\vec{e}_{i} \in \mathbf{F}_{2^{t}}^{n}$ be the $i$ th unit vector and $N=m^{h}$, where

$$
\begin{equation*}
h=\exp \left(O\left(\sqrt[r]{(\log n) \cdot(\log \log n)^{r-1}}\right)\right)=n^{O\left((\log \log n / \log n)^{1-1 / r}\right)} \tag{1}
\end{equation*}
$$

Let $\mathcal{U}=\left\{\vec{u}_{1}, \vec{u}_{2}, \ldots, \vec{u}_{n}\right\}$ be a family of $S_{m}$-matching vectors, where $\vec{u}_{i} \in \mathbf{Z}_{m}^{h}$ for each $i \in[1, n]$. We define a code $C: \mathbf{F}_{2^{t}}^{n} \rightarrow \mathbf{F}_{2^{t}}^{N}$ as follows: For any $\vec{x}=\left(x_{1}, x_{2}, \ldots, x_{n}\right) \in \mathbf{F}_{2^{t}}^{n}$, let $C(\vec{x})=x_{1} C\left(\vec{e}_{1}\right)+$ $x_{2} C\left(\vec{e}_{2}\right)+\cdots+x_{n} C\left(\vec{e}_{n}\right)$, where for each $i \in[1, n]$,

$$
\begin{equation*}
C\left(\vec{e}_{i}\right)=\left(\gamma^{\left\langle\vec{u}_{i}, \vec{z}\right\rangle_{m}}\right)_{\vec{z} \in \mathbf{Z}_{m}^{h}} \tag{2}
\end{equation*}
$$

Input: A vector $\vec{y} \in \mathbf{F}_{2^{t}}^{N}$.
Step 1: Choose $\vec{v} \in \mathbf{Z}_{m}^{h}$ uniformly at random.
Step 2: Query $\vec{y}(\vec{v}), \vec{y}\left(\vec{v}+b_{1} \vec{u}_{i}\right), \ldots, \vec{y}\left(\vec{v}+b_{k-1} \vec{u}_{i}\right) \in \mathbf{F}_{2^{t}}$, where $\vec{y}(\vec{z})$ denotes the symbol of $\vec{y} \in$ $\mathbf{F}_{2^{t}}^{N}$ indexed by $\vec{z} \in \mathbf{Z}_{m}^{h}$.
Step 3: Output $x_{i}=\gamma^{-\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}}\left\{a_{0} \cdot \vec{y}(\vec{v})+a_{1} \cdot \vec{y}\left(\vec{v}+b_{1} \vec{u}_{i}\right)+\cdots+a_{k-1} \cdot \vec{y}\left(\vec{v}+b_{k-1} \vec{u}_{i}\right)\right\}$.

Figure 1: Decoding Algorithm $D_{i}$

### 3.2 Decoding

For each $i \in[1, n]$, a randomized decoding algorithm $D_{i}: \mathbf{F}_{2^{t}}^{N} \rightarrow \mathbf{F}_{2^{t}}$ is defined as in Figure 1,
Lemma 3.1 ([7, Lemma 3.5]) The decoding algorithm $\mathcal{D}=\left\{D_{i}\right\}_{i \in[1, n]}$ is a perfectly smooth decoder.

To be self-contained, we show the proof of Lemma 3.1 in Appendix A. Thus from Lemmas 2.2 and 2.5. we have the following result:

Theorem 3.1 ([7, Theorem 3.6]) For any integer $n>1$ and any integer $r>1$, there exists a $k$-query locally decodable code $C: \mathbf{F}_{2^{t}}^{n} \rightarrow \mathbf{F}_{2^{t}}^{N}$ such that $k \leq 2^{r}$ and

$$
N=\exp \left(\exp \left(O\left(\sqrt[r]{\log n \cdot(\log \log n)^{r-1}}\right)\right)\right)=\exp \left(n^{O\left((\log \log n / \log n)^{1-1 / r}\right)}\right)
$$

## 4 Query-Efficient Locally Decodable Codes

### 4.1 How to Reduce the Number of Queries

By setting $r=2$ in Theorem 3.1, it is immediate to see that for any integer $n>1$, there exists a 4query locally decodable code $C: \mathbf{F}_{2^{t}}^{n} \rightarrow \mathbf{F}_{2^{t}}^{N}$ such that

$$
\begin{equation*}
N=\exp (\exp (O(\sqrt{\log n \cdot \log \log n})))=\exp \left(n^{O\left((\log \log n / \log n)^{1 / 2}\right)}\right) \tag{3}
\end{equation*}
$$

On the other hand, Efremenko [7, Example 3.7] found a surprising example: Let $m=511=2^{9}-1=$ $7 \cdot 73$ and $S_{511}=\{1,365,147\}$. For the integer $m=511$, determine a finite field $\mathbf{F}_{2^{t}}$ and an element $\gamma \in \mathbf{F}_{2^{t}}$ of order $m=511$ by Lemma 2.3. Indeed, the finite field $\mathbf{F}_{2^{t}}$ is $\mathbf{F}_{2^{9}}=\mathbf{F}_{2}[\gamma] /\left(\gamma^{9}+\gamma^{4}+1\right)$ and $\gamma \in \mathbf{F}_{2^{9}}$ is an element of order 511. For the integer $m=511$, there exists an $S_{511}$-decoding polynomial $P(x)=\gamma^{423} \cdot x^{65}+\gamma^{257} \cdot x^{12}+\gamma^{342}$ with 3 monomials, which implies that for any $n>1$, there exists a 3query locally decodable code $C: \mathbf{F}_{2^{9}}^{n} \rightarrow \mathbf{F}_{2^{9}}^{N}$, where $N$ is given by (3).

The result above for the integer $m=511$ is special. For an integer $m=15=2^{4}-1=3 \cdot 5$, let $S_{15}=\{1,10,6\}$ and by Lemma 2.3, we take the finite field $\mathbf{F}_{2^{t}}$ to be $\mathbf{F}_{2^{4}}=\mathbf{F}_{2}[\gamma] /\left(\gamma^{4}+\gamma+1\right)$ and the element $\gamma \in \mathbf{F}_{2^{4}}$ of order 15 . By an exhaustive search, we can verify that for the integer $m=15$, there does not exist an $S_{15}$-decoding polynomial with less than 4 monomials. From these observations, we see that it is impossible for every odd integer $m=p_{1}^{e_{1}} p_{2}^{e_{2}}$ to have an $S_{m}$-decoding polynomial with less than 4 monomials. Thus for an odd integer $m=p_{1}^{e_{1}} p_{2}^{e_{2}} \cdots p_{r}^{e_{r}}$, we need to find structural properties of $S_{m}$-decoding polynomials to reduce the number of queries to less than $2^{r}$.

### 4.2 Building Blocks for Query-Efficient Locally Decodable Codes

In this section, we present a new construction for query-efficient locally decodable codes of subexponential length. A key idea of our construction is to generate a $k_{1} k_{2}$-locally decodable code by composing a $k_{1}$-locally decodable code and a $k_{2}$-locally decodable code.

Let $m_{1}=p_{1}^{e_{1}} p_{2}^{e_{2}} \cdots p_{r}^{e_{r}}$ be a product of $r>1$ distinct odd primes and $m_{2}=q_{1}^{c_{1}} q_{2}^{c_{2}} \cdots q_{\ell}^{c_{\ell}}$ be a product of $\ell>1$ distinct odd primes. Assume that $\operatorname{gcd}\left(m_{1}, m_{2}\right)=1$ in the rest of this paper and let $m=$ $m_{1} m_{2}$ be a product of $r+\ell>2$ distinct odd primes. From Lemma 2.3, we know that (1) for the odd integer $m_{1}$, there exist a finite field $\mathbf{F}_{2^{t_{1}}}$ with $t_{1} \in\left[1, m_{1}-1\right]$ and an element $\gamma_{1} \in \mathbf{F}_{2^{t_{1}}}$ of order $m_{1}$; (2) for the odd integer $m_{2}$, there exist a finite field $\mathbf{F}_{2^{t_{2}}}$ with $t_{2} \in\left[1, m_{2}-1\right]$ and an element $\gamma_{2} \in \mathbf{F}_{2^{t_{2}}}$ of order $m_{2}$; (3) for the odd integer $m=m_{1} m_{2}$, there exist a finite field $\mathbf{F}_{2^{t}}$ with $t \in[1, m-1]$ and an element $\gamma \in \mathbf{F}_{2^{t}}$ of order $m$. The following lemmas are crucial for our construction.

Lemma 4.1 For the finite fields $\mathbf{F}_{2^{t_{1}}}, \mathbf{F}_{2^{t_{2}}}$, and $\mathbf{F}_{2^{t}}$, the following holds: (1) $\mathbf{F}_{2^{t_{1}}}$ is a subfield of $\mathbf{F}_{2^{t}}$; (2) $\mathbf{F}_{2^{t_{2}}}$ is a subfield of $\mathbf{F}_{2^{t}}$; (3) $t=\operatorname{lcm}\left(t_{1}, t_{2}\right)$.

Proof: For the statement (1), it is immediate that $\mathbf{F}_{2^{t_{1}}}$ is a subfield of $\mathbf{F}_{2^{t}}$ iff $t$ is divisible by $t_{1}$. Note that $t_{1} \in\left[1, m_{1}-1\right]$ is a minimum integer such that $2^{t_{1}} \equiv 1\left(\bmod m_{1}\right)$ and $t \in[1, m-1]$ is a minimum integer such that $2^{t} \equiv 1(\bmod m)$. Assume that $t$ is not divisible by $t_{1}$, i.e., there exist $q \geq 1$ and $0<r<t_{1}$ such that $t=q t_{1}+r$. Since $m=m_{1} m_{2}$, we have that $2^{t} \equiv 1\left(\bmod m_{1}\right)$. So from the fact that $2^{t_{1}} \equiv 1\left(\bmod m_{1}\right)$, it follows that $1 \equiv 2^{t} \equiv 2^{q t_{1}+r} \equiv\left(2^{t_{1}}\right)^{q} \cdot 2^{r} \equiv 2^{r}\left(\bmod m_{1}\right)$. This contradicts the fact that $t_{1} \in\left[1, m_{1}-1\right]$ is a minimum integer such that $2^{t_{1}} \equiv 1\left(\bmod m_{1}\right)$. Thus $t$ is divisible by $t_{1}$, which completes the proof of the statement (1). The proof of the statement (2) is analogous to that of the statement (1). The statement (3) follows from the statements (1) and (2) and the fact that $t \in[1, m-1]$ is a minimum integer such that $2^{t} \equiv 1(\bmod m)$.

For the finite field $\mathbf{F}_{2^{t_{1}}}$ and the element $\gamma \in \mathbf{F}_{2^{t}}$ given by Lemma 4.1, the following claims hold:

Claim 4.1 For every $h \in \mathbf{Z}_{m_{1}}^{*}$, $\gamma^{h m_{2}} \in \mathbf{F}_{2^{t_{1}}}$ is an element of order $m_{1}$.
Proof: Since $2^{t_{1}} \equiv 1\left(\bmod m_{1}\right)$, there exists $q \geq 1$ such that $2^{t_{1}}-1=q m_{1}$. From the fact that $\gamma \in$ $\mathbf{F}_{2}^{t}$ is an element of order $m=m_{1} m_{2}$, we have that for every $h \in \mathbf{Z}_{m_{1}}^{*}$,

$$
\left(\gamma^{h m_{2}}\right)^{2^{t_{1}-1}}=\left(\gamma^{h m_{2}}\right)^{q m_{1}}=\left(\gamma^{m_{1} m_{2}}\right)^{h}=\left(\gamma^{m}\right)^{h}=1
$$

which implies that $\gamma^{h m_{2}} \in \mathbf{F}_{2^{t_{1}}}$. It is immediate that $\left(\gamma^{h m_{2}}\right)^{m_{1}}=\left(\gamma^{m_{1} m_{2}}\right)^{h}=\left(\gamma^{m}\right)^{h}=1$. By contradiction, we show that for every $h \in \mathbf{Z}_{m_{1}}^{*}$, the order of $\gamma^{h m_{2}} \in \mathbf{F}_{2^{t_{1}}}$ is $m_{1}$ Assume that there exists an $h \in \mathbf{Z}_{m_{1}}^{*}$ such that the order of $\gamma^{h m_{2}}$ is $0<\ell<m_{1}$, i.e., $\left(\gamma^{h m_{2}}\right)^{\ell}=\gamma^{h \ell m_{2}}=1$. Since the order of $\gamma \in$ $\mathbf{F}_{2^{t}}$ is $m$, we have that $h \ell m_{2}$ is divisible by $m=m_{1} m_{2}$, i.e., $h \ell$ is divisible by $m_{1}$. From the fact that $h \in \mathbf{Z}_{m_{1}}^{*}$, it follows that $\ell$ is divisible by $m_{1}$, which contradicts the assumption that $0<\ell<m_{1}$.
Claim 4.2 In the finite field $\mathbf{F}_{2^{t_{1}}}$, there exist exactly $\left|\mathbf{Z}_{m_{1}}^{*}\right|$ elements of order $m_{1}$.
Proof: For an element $g \in \mathbf{F}_{2^{t_{1}}}$ of order $2^{t_{1}}-1$, we have that $\alpha=g^{\left(2^{t_{1}}-1\right) / m_{1}} \in \mathbf{F}_{2^{t_{1}}}$ is an element of order $m_{1}$. So the $m_{1}$ elements $\alpha^{0}, \alpha^{1}, \ldots, \alpha^{m_{1}-1}$ are the set of all elements that satisfies $x^{m_{1}}=1$. It is immediate that for each $j \in \mathbf{Z}_{m}$, the order of $\alpha^{j}$ is $m_{1} / \operatorname{gcd}\left(j, m_{1}\right)$. This implies that in the finite field $\mathbf{F}_{2^{t_{1}}}$, there exist exactly $\left|\mathbf{Z}_{m_{1}}^{*}\right|$ elements of order $m_{1}$.

In a way similar to the proofs of Claims 4.1 and 4.2, we can also show the following claims for the finite field $\mathbf{F}_{2^{t_{2}}}$ and the element $\gamma \in \mathbf{F}_{2^{t}}$ determined by Lemma 4.1.

Claim 4.3 For every $h \in \mathbf{Z}_{m_{2}}^{*}, \gamma^{h m_{1}} \in \mathbf{F}_{2^{t_{2}}}$ is an element of order $m_{2}$.
Claim 4.4 In the finite field $\mathbf{F}_{2^{t_{2}}}$, there exist $\left|\mathbf{Z}_{m_{2}}^{*}\right|$ elements of order $m_{2}$.
From Claims 4.1, 4.2, 4.3, and 4.4, we can show the following lemma:
Lemma 4.2 For the elements $\gamma_{1} \in \mathbf{F}_{2^{t_{1}}}, \gamma_{2} \in \mathbf{F}_{2^{t_{2}}}$, and $\gamma \in \mathbf{F}_{2^{t}}$, the following holds: (1) there exists $h_{1} \in \mathbf{Z}_{m_{1}}^{*}$ such that $\gamma_{1}=\gamma^{h_{1} m_{2}} ;$ (2) there exists $h_{2} \in \mathbf{Z}_{m_{2}}^{*}$ such that $\gamma_{2}=\gamma^{h_{2} m_{1}}$.

Proof: The statement (1) immediately follows from Claims 4.1 and 4.2 and the statement (2) immediately follows from Claims 4.3 and 4.4 .

Let $S_{m_{1}}=\left\{s_{1}^{1}, s_{2}^{1}, \ldots, s_{2^{r}-1}^{1}\right\}, S_{m_{2}}=\left\{s_{1}^{2}, s_{2}^{2}, \ldots, s_{2^{\ell}-1}^{2}\right\}$, and $S_{m}=\left\{s_{1}, s_{2}, \ldots, s_{2^{r+\ell}{ }_{-1}}\right\}$ be the canonical sets of the integers $m_{1}, m_{2}$, and $m$, respectively, and let $s_{0}^{1}=s_{0}^{2}=s_{0}=0$.

Lemma 4.3 For the sets $S_{m_{1}}, S_{m_{2}}$, and $S_{m}$, the following holds: For any $s \in S_{m} \cup\{0\}$, (1) $s \in S_{m}$ iff there exist $s_{i_{1}}^{1} \in S_{m_{1}} \cup\{0\}$ and $s_{i_{2}}^{2} \in S_{m_{2}} \cup\{0\}$ such that $s \equiv s_{i_{1}}^{1}\left(\bmod m_{1}\right)$, $s \equiv s_{i_{2}}^{2}\left(\bmod m_{2}\right)$, and either $s_{i_{1}}^{1} \neq 0$ or $s_{i_{2}}^{2} \neq 0 ;(2) s=0$ iff $s \equiv 0\left(\bmod m_{1}\right)$ and $s \equiv 0\left(\bmod m_{2}\right)$.
Proof: It follows from the definitions of $S_{m_{1}}, S_{m_{2}}$, and $S_{m}$ and the Chinese Remainder Theorem.

### 4.3 Constructions for Query-Efficient Locally Decodable Codes

For the integers $m_{1}, m_{2}$, and $m$ and the integer $h>0$ given by (1), let $N_{1}=m_{1}^{h}, N_{2}=m_{2}^{h}$, and $N=$ $m^{h}$, respectively. The following is essential to construct query-efficient locally decodable codes.

Theorem 4.1 ((Composition Theorem)) Let $C_{1}: \mathbf{F}_{2^{t_{1}}}^{n} \rightarrow \mathbf{F}_{2^{t_{1}}}^{N_{1}}$ be a $k_{1}$-query locally decodable code that has an $S_{m_{1}}$-decoding polynomial $P_{1}(x) \in \mathbf{F}_{2^{t_{1}}}[x] \subseteq \mathbf{F}_{2^{t}}[x]$ with $k_{1}$ monomials and $C_{2}: \mathbf{F}_{2^{t_{2}}}^{n} \rightarrow$ $\mathbf{F}_{2^{t_{2}}}^{N_{2}}$ be a $k_{2}$-query locally decodable code that has an $S_{m_{2}}$-decoding polynomial $P_{2}(x) \in \mathbf{F}_{2^{t_{2}}}[x] \subseteq$ $\mathbf{F}_{2^{t}}[x]$ with $k_{2}$ monomials. Then we can construct a $k$-query locally decodable code $C: \mathbf{F}_{2^{t}}^{n} \rightarrow \mathbf{F}_{2^{t}}^{N}$ that has an $S_{m}$-decoding polynomial $P(x) \in \mathbf{F}_{2^{t}}[x]$ with $k$ monomials, where $k \leq k_{1} k_{2}$.

Proof: For $m=m_{1} m_{2}$ and $h$ given by (11), we define $C: \mathbf{F}_{2^{t}}^{n} \rightarrow \mathbf{F}_{2^{t}}^{N}$ as follows: For any vector $\vec{x}=$ $\left(x_{1}, x_{2}, \ldots, x_{n}\right) \in \mathbf{F}_{2^{t}}$, let $C(\vec{x})=x_{1} C\left(\vec{e}_{1}\right)+x_{2} C\left(\vec{e}_{2}\right)+\cdots+x_{n} C\left(\vec{e}_{n}\right)$, where for each $i \in[1, n], C\left(\vec{e}_{i}\right)$ is given by (2). For the integer $h_{1} \in \mathbf{Z}_{m_{1}}^{*}$ determined by Lemma4.2-(1) and the integer $h_{2} \in \mathbf{Z}_{m_{2}}^{*}$ determined by Lemma 4.2+(2), let $P(x)=P_{1}\left(x^{h_{1} m_{2}}\right) \cdot P_{2}\left(x^{h_{2} m_{1}}\right)$. It is obvious that $P(x)$ is a polynomial with $k \leq k_{1} k_{2}$ monomials. Let $P(x)=a_{0}+a_{1} x^{b_{1}}+\cdots+a_{k-1} x^{k-1}$. For each $i \in[1, n]$, a randomized decoding algorithm $D_{i}$ is defined exactly the same as Figure 1. For each $i \in[1, n]$, we have that

$$
\begin{aligned}
D_{i}(C(\vec{x})) & =D_{i}\left(x_{1} C\left(\vec{e}_{1}\right)+x_{2} C\left(\vec{e}_{2}\right)+\cdots+x_{n} C\left(\vec{e}_{n}\right)\right) \\
& =x_{1} D_{i}\left(C\left(\vec{e}_{1}\right)\right)+x_{2} D_{i}\left(C\left(\vec{e}_{2}\right)\right)+\cdots+x_{n} D_{i}\left(C\left(\vec{e}_{n}\right)\right) .
\end{aligned}
$$

Thus it suffices to show that $\operatorname{Pr}\left[D_{i}\left(C\left(\vec{e}_{i}\right)\right)=1\right]=1$ for each $i \in[1, n]$ and $\operatorname{Pr}\left[D_{i}\left(C\left(\vec{e}_{j}\right)\right)=0\right]=1$ for each $j \in[1, n] \backslash\{i\}$. From (2), it follows that for queries $\vec{v}, \vec{v}+b_{1} \vec{u}_{i}, \ldots, \vec{v}+b_{k-1} \vec{u}_{i} \in Z_{m}^{h}$,

$$
\begin{aligned}
D_{i}\left(C\left(\vec{e}_{i}\right)\right) & =\gamma^{-\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \cdot\left(a_{0} \gamma^{\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}}+a_{1} \gamma^{\left\langle\vec{u}_{i}, \vec{v}+b_{1} \vec{u}_{i}\right\rangle_{m}}+\cdots+a_{k-1} \gamma^{\left\langle\vec{u}_{i}, \vec{v}+b_{k-1} \vec{u}_{i}\right\rangle_{m}}\right) \\
& =\gamma^{-\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \cdot\left(a_{0} \gamma^{\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}}+a_{1} \gamma^{\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \gamma^{b_{1}\left\langle\vec{u}_{i}, \vec{u}_{i}\right\rangle_{m}}+\cdots+a_{k-1} \gamma^{\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \gamma^{b_{k-1}\left\langle\vec{u}_{i}, \vec{u}_{i}\right\rangle_{m}}\right) \\
& =a_{0}+a_{1} \gamma^{b_{1}\left\langle\vec{u}_{i}, \vec{u}_{i}\right\rangle_{m}}+\cdots+a_{k-1} \gamma^{b_{k-1}\left\langle\vec{u}_{i}, \vec{u}_{i}\right\rangle_{m}} \\
& =P\left(\gamma^{\left\langle\vec{u}_{i}, \vec{u}_{i}\right\rangle_{m}}\right)=P(1)=P_{1}(1) \cdot P_{2}(1)=1 ;
\end{aligned}
$$

$$
\begin{align*}
D_{i}\left(C\left(\vec{e}_{j}\right)\right) & =\gamma^{-\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \cdot\left(a_{0} \gamma^{\left\langle\vec{u}_{j}, \vec{v}\right\rangle_{m}}+a_{1} \gamma^{\left\langle\vec{u}_{j}, \vec{v}+b_{1} \vec{u}_{i}\right\rangle_{m}}+\cdots+a_{k-1} \gamma^{\left\langle\vec{u}_{j}, \vec{v}+b_{k-1} \vec{u}_{i}\right\rangle_{m}}\right) \\
& =\gamma^{-\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \cdot\left(a_{0} \gamma^{\left\langle\vec{u}_{j}, \vec{v}\right\rangle_{m}}+a_{1} \gamma^{\left\langle\vec{u}_{j}, \vec{v}\right\rangle_{m}} \gamma^{b_{1}\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}+\cdots+a_{k-1} \gamma^{\left\langle\vec{u}_{j}, \vec{v}\right\rangle_{m}} \gamma^{b_{k-1}\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}\right) \\
& =\gamma^{-\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \cdot \gamma^{\left\langle\vec{u}_{j}, \vec{v}\right\rangle_{m}} \cdot\left(a_{0}+a_{1} \gamma^{b_{1}\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}+\cdots+a_{k-1} \gamma^{b_{k-1}\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}\right) \cdot \\
& =\gamma^{-\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \cdot \gamma^{\left\langle\vec{u}_{j}, \vec{v}\right\rangle_{m}} \cdot P\left(\gamma^{\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}\right) \\
& =\gamma^{-\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \cdot \gamma^{\left\langle\vec{u}_{j}, \vec{v}\right\rangle_{m}} \cdot P_{1}\left(\gamma^{h_{1} m_{2}\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}\right) \cdot P_{2}\left(\gamma^{h_{2} m_{1}\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}\right) \\
& =\gamma^{-\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \cdot \gamma^{\left\langle\vec{u}_{j}, \vec{v}\right\rangle_{m}} \cdot P_{1}\left(\gamma_{1}^{\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}\right) \cdot P_{2}\left(\gamma_{2}^{\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}\right), \tag{4}
\end{align*}
$$

where (4) follows from Lemma 4.2. Since $\mathcal{U}=\left\{\vec{u}_{1}, \vec{u}_{2}, \ldots, \vec{u}_{n}\right\}$ is a family of $S_{m}$-matching vectors, we have that $\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m} \in S_{m}$. Thus from Lemma 4.3, it follows that there exist $s_{i_{1}}^{1} \in S_{m_{1}} \cup\{0\}$ and $s_{i_{2}}^{2} \in$ $S_{m_{2}} \cup\{0\}$ such that $\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m} \equiv s_{i_{1}}^{1}\left(\bmod m_{1}\right),\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m} \equiv s_{i_{2}}^{2}\left(\bmod m_{2}\right)$, and either $s_{i_{1}}^{1} \neq 0$ or $s_{i_{2}}^{2} \neq 0$. Recall that $\gamma_{1} \in \mathbf{F}_{2^{t_{1}}}$ is an element of order $m_{1} ; \gamma_{2} \in \mathbf{F}_{2^{t_{2}}}$ is an element of order $m_{2} ; P_{1}(x)$ is an $S_{m_{1}}$ decoding polynomial; $P_{2}(x)$ is an $S_{m_{2}}$-decoding polynomial. Then from (4), we have that

$$
P_{1}\left(\gamma_{1}^{\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}\right)=P_{1}\left(\gamma_{1}^{s_{i_{1}}^{1}}\right)=0 \bigvee P_{2}\left(\gamma_{2}^{\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}\right)=P_{2}\left(\gamma_{1}^{s_{i_{2}}^{2}}\right)=0 .
$$

Thus it follows that $D_{i}\left(C\left(\overrightarrow{e_{i}}\right)\right)=1$ for each $i \in[1, n]$ and $D_{i}\left(C\left(\vec{e}_{j}\right)\right)=0$ for each $j \in[1, n] \backslash\{i\}$.
Corollary 4.1 ((to Theorem 4.1)) For any integer $n>1$ and any integer $r>1$, there exists a $k$-query locally decodable code $C: \mathbf{F}_{2^{t}}^{n} \rightarrow \mathbf{F}_{2^{t}}^{N}$ such that $k \leq 3 \cdot 2^{r-2}$ and

$$
N=\exp \left(\exp \left(O\left(\sqrt[r]{\log n \cdot(\log \log n)^{r-1}}\right)\right)\right)=\exp \left(n^{O\left((\log \log n / \log n)^{1-1 / r}\right)}\right)
$$

Proof: Efremenko [7, Example 3.7] showed that for an odd integer $m_{1}=511=7 \cdot 73$, there exists a 3query locally decodable code $C_{1}: \mathbf{F}_{2^{t_{1}}}^{n} \rightarrow \mathbf{F}_{2^{t_{1}}}^{N_{1}}$ that has an $S_{m_{1}}$-decoding polynomial $P_{1}(x) \in \mathbf{F}_{2^{t_{1}}}[x]$ with 3 monomials. For any integer $r>1$, we take $m_{2}=p_{1}^{e_{1}} p_{2}^{e_{2}} \cdots p_{r-2}^{e_{r-2}}$ that is a product of $r-2$ distinct odd primes such that $\operatorname{gcd}\left(m_{1}, m_{2}\right)=1$, and let $m=m_{1} m_{2}$. Efremenko [7, Theorem 3.6] also derived that for any integer $r>1$, there exists a $k_{2}$-query locally decodable code $C_{1}: \mathbf{F}_{2^{t_{1}}}^{n} \rightarrow \mathbf{F}_{2^{t_{1}}}^{N_{1}}$ that has an $S_{m_{2}}$-decoding polynomial $P_{2}(x) \in \mathbf{F}_{2^{t_{2}}}[x]$ with $k_{2}$ monomials, where $k_{2} \leq 2^{r}$. So from Theorem 4.1, we can construct a $k$-query locally decodable code $C: \mathbf{F}_{2^{t}}^{n} \rightarrow \mathbf{F}_{2^{t}}^{N}$ that has an $S_{m^{\prime}}$-decoding polynomial $P(x) \in \mathbf{F}_{2^{t}}[x]$ with $k$ monomials, where $k \leq 3 \cdot 2^{r-2}$.

## 5 Concluding Remarks

In this paper, we have shown the Composition Theorem that constructs a $k_{1} k_{2}$-query locally decodable code by composing a $k_{1}$-query locally decodable code and a $k_{2}$-query locally decodable code (see Theorem 4.1) and in Corollary 4.1, we have also shown that for any integer $r>1$, there exists a $k$ query locally decodable code $C: \mathbf{F}_{2^{t}}^{n} \rightarrow \mathbf{F}_{2^{t}}^{N}$ such that $k \leq 3 \cdot 2^{r-2}$ and

$$
N=\exp \left(\exp \left(O\left(\sqrt[r]{\log n \cdot(\log \log n)^{r-1}}\right)\right)\right)=\exp \left(n^{O\left((\log \log n / \log n)^{1-1 / r}\right)}\right)
$$

For perfectly smooth decoders, we can immediately modify Theorem 4.1 as follows:

Theorem 5.1 Let $C_{1}: \mathbf{F}_{2^{t_{1}}}^{n} \rightarrow \mathbf{F}_{2^{t_{1}}}^{N_{1}}$ be a $k_{1}$-query locally decodable code with a perfectly smooth decoder $\mathcal{D}_{1}$ that has an $S_{m_{1}}$-decoding polynomial $P_{1}(x) \in \mathbf{F}_{2^{t_{1}}}[x] \subseteq \mathbf{F}_{2^{t}}[x]$ with $k_{1}$ monomials and $C_{2}: \mathbf{F}_{2^{t_{2}}}^{n} \rightarrow \mathbf{F}_{2^{t_{1}}}^{N_{2}}$ be a $k_{2}$-query locally decodable code with a perfectly smooth decoder $\mathcal{D}_{2}$ that has an $S_{m_{2}}$-decoding polynomial $P_{2}(x) \in \mathbf{F}_{2^{t_{2}}}[x] \subseteq \mathbf{F}_{2^{t}}[x]$ with $k_{2}$ monomials. Then we can construct a $k$ query locally decodable code $C: \mathbf{F}_{2^{t}}^{n} \rightarrow \mathbf{F}_{2^{t}}^{N}$ with a perfectly smooth decoder $\mathcal{D}$ that has an $S_{m}$-decoding polynomial $P(x) \in \mathbf{F}_{2^{t}}[x]$ with $k$ monomials, where $k \leq k_{1} k_{2}$.

From Theorem 5.1] and the transformation [21] from a $k$-query locally decodable codes with a perfectly smooth decoder to $k$-server private information retrieval, we can show the following theorem:

Theorem 5.2 For any integer $n>1$ and any integer $r>1$, there exists a $k$-server private information retrieval such that $k \leq 3 \cdot 2^{r-2}$ and $C_{k}(n)=n^{O\left((\log \log n / \log n)^{(r-1) / r}\right)}$.

At present, we know only a 3-query locally decodable code $\mathbf{F}_{2^{9}}^{n} \rightarrow \mathbf{F}_{2^{9}}^{N}$ such that

$$
N=\exp (\exp (O(\sqrt{\log n \cdot \log \log n})))=\exp \left(n^{O\left((\log \log n / \log n)^{1 / 2}\right)}\right)
$$

for an add integer $m=511=2^{9}=7 \cdot 73$ [7, Example 3.7]. Let $\mathcal{M}_{r}$ be a set of integers, each of which is a product of $r>1$ distinct odd primes. From the Composition Theorem (see Theorem4.1), it follows that if there exist $m_{1}, m_{2}, \ldots, m_{\ell} \in \mathcal{M}_{2}$ such that $\operatorname{gcd}\left(m_{i}, m_{j}\right)=1$ for each $1 \leq i<j \leq \ell$ and each $m_{i} \in \mathcal{M}_{2}$ generates a 3-query locally decodable code $C_{i}: \mathbf{F}_{2^{t_{i}}}^{n} \rightarrow \mathbf{F}_{2^{t_{i}}}^{N}$ that has an $S_{m_{i}}$-decoding polynomial $P_{i}(x) \in \mathbf{F}_{2^{t_{i}}}[x]$ with less than 4 monomials, where

$$
N=\exp (\exp (O(\sqrt{\log n \cdot \log \log n})))=\exp \left(n^{O\left((\log \log n / \log n)^{1 / 2}\right)}\right)
$$

then for the integer $m=m_{1} m_{2} \cdots m_{\ell}$, we can construct a $k$-query locally decodable code $C: \mathbf{F}_{2^{t}}^{n} \rightarrow$ $\mathbf{F}_{2^{t}}^{N}$ that has an $S_{m^{\prime}}$-decoding polynomial $P(x) \in \mathbf{F}_{2^{t}}[x]$ with $k$ monomials, where $k \leq 3^{\ell}$ and

$$
N=\exp (\exp (O(\sqrt[2 \ell]{\log n \cdot \log \log n})))=\exp \left(n^{O\left((\log \log n / \log n)^{1-1 / 2 \ell}\right)}\right)
$$

however, we do not know such integers $m_{1}, m_{2}, \ldots, m_{\ell} \in \mathcal{M}_{2}$ exist other than $m=511 \in \mathcal{M}_{2}$. Thus the following problems are both of theoretical interest and of practical importance.
(1) Find integers $m \in \mathcal{M}_{2} \backslash\{511\}$ that generate a 3-query locally decodable code $C: \mathbf{F}_{2^{t}}^{n} \rightarrow \mathbf{F}_{2^{t}}^{N}$, i.e., the code $C$ has an $S_{m^{\prime}}$-decoding polynomial $P(x) \in \mathbf{F}_{2^{t}}[x]$ with less than 4 monomials.
(2) For any integer $r>2$, find an integer $m \in \mathcal{M}_{r}$ that generate a $k$-query locally decodable code $C: \mathbf{F}_{2^{t}}^{n} \rightarrow \mathbf{F}_{2^{t}}^{N}$ that has an $S_{m}$-decoding polynomial $P(x) \in \mathbf{F}_{2^{t}}[x]$ with $k<3 \cdot 2^{r-2}$ monomials.

## Acknowledgments

The authors would like to thank Osamu Watanabe for his insightful discussions and valuable comments for the earlier version of the paper.

## A Proof of Lemma 3.1

For each $i \in[1, n]$, it is obvious that each of queries $\vec{v}, \vec{v}+b_{1} \vec{u}_{i}, \ldots, \vec{v}+b_{k-1} \vec{u}_{i} \in Z_{m}^{h}$ is uniformly distributed over $[1, N]$. So for any vector $\vec{x}=\left(x_{1}, x_{2}, \ldots, x_{n}\right) \in \mathbf{F}_{2^{t}}^{n}$, we show that $\operatorname{Pr}\left[D_{i}(C(\vec{x}))=x_{i}\right]=$ 1 for each $i \in[1, n]$. Since $C(\vec{x})=x_{1} C\left(\vec{e}_{1}\right)+x_{2} C\left(\vec{e}_{2}\right)+\cdots+x_{n} C\left(\vec{e}_{n}\right)$, we have that for each $i \in[1, n]$,

$$
\begin{aligned}
D_{i}(C(\vec{x})) & =D_{i}\left(x_{1} C\left(\vec{e}_{1}\right)+x_{2} C\left(\vec{e}_{2}\right)+\cdots+x_{n} C\left(\vec{e}_{n}\right)\right) \\
& =x_{1} D_{i}\left(C\left(\vec{e}_{1}\right)\right)+x_{2} D_{i}\left(C\left(\vec{e}_{2}\right)\right)+\cdots+x_{n} D_{i}\left(C\left(\vec{e}_{n}\right)\right) .
\end{aligned}
$$

Thus it suffices to show that $\operatorname{Pr}\left[D_{i}\left(C\left(\vec{e}_{i}\right)\right)=1\right]=1$ for each $i \in[1, n]$ and $\operatorname{Pr}\left[D_{i}\left(C\left(\vec{e}_{j}\right)\right)=0\right]=1$ for each $j \in[1, n] \backslash\{i\}$. From (2), it follows that for queries $\vec{v}, \vec{v}+b_{1} \vec{u}_{i}, \ldots, \vec{v}+b_{k-1} \vec{u}_{i} \in Z_{m}^{h}$,

$$
D_{i}\left(C\left(\vec{e}_{i}\right)\right)=\gamma^{-\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \cdot\left(a_{0} \gamma^{\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}}+a_{1} \gamma^{\left\langle\vec{u}_{i}, \vec{v}+b_{1} \vec{u}_{i}\right\rangle_{m}}+\cdots+a_{k-1} \gamma^{\left\langle\vec{u}_{i}, \vec{v}+b_{k-1} \vec{u}_{i}\right\rangle_{m}}\right)
$$

$$
\begin{align*}
& =\gamma^{-\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \cdot\left(a_{0} \gamma^{\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}}+a_{1} \gamma^{\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \gamma^{b_{1}\left\langle\vec{u}_{i}, \vec{u}_{i}\right\rangle_{m}}+\cdots+a_{k-1} \gamma^{\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \gamma^{b_{k-1}\left\langle\vec{u}_{i}, \vec{u}_{i}\right\rangle_{m}}\right) \\
& =a_{0}+a_{1} \gamma^{b_{1}\left\langle\vec{u}_{i}, \vec{u}_{i}\right\rangle_{m}}+\cdots+a_{k-1} \gamma^{b_{k-1}\left\langle\vec{u}_{i}, \vec{u}_{i}\right\rangle_{m}} \\
& =P\left(\gamma^{\left\langle\vec{u}_{i}, \vec{u}_{i}\right\rangle_{m}}\right) ;  \tag{5}\\
D_{i}\left(C\left(\vec{e}_{j}\right)\right) & =\gamma^{-\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \cdot\left(a_{0} \gamma^{\left\langle\vec{u}_{j}, \vec{v}\right\rangle_{m}}+a_{1} \gamma^{\left\langle\vec{u}_{j}, \vec{v}+b_{1} \vec{u}_{i_{2}}\right\rangle_{m}}+\cdots+a_{k-1} \gamma^{\left\langle\vec{u}_{j}, \vec{v}+b_{k-1} \vec{u}_{i}\right\rangle_{m}}\right) \\
& =\gamma^{\left\langle\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}\right.} \cdot\left(a_{0} \gamma^{\left\langle\vec{u}_{j}, \vec{v}\right\rangle_{m}}+a_{1} \gamma^{\left\langle\vec{u}_{j}, \vec{v}\right\rangle_{m}} \gamma^{b_{1}\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}+\cdots+a_{k-1} \gamma^{\left\langle\vec{u}_{j}, \vec{v}\right\rangle_{m}} \gamma^{b_{k-1}\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}\right) \\
& =\gamma^{-\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \cdot \gamma^{\left\langle\vec{u}_{j}, \vec{v}\right\rangle_{m}} \cdot\left(a_{0}+a_{1} \gamma_{1}^{b_{1}\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}+\cdots+a_{k-1}^{b_{k-1}\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}\right) . \\
& =\gamma^{-\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \cdot \gamma^{\left\langle\vec{u}_{j}, \vec{v}\right\rangle_{m}} \cdot P\left(\gamma^{\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}\right) . \tag{6}
\end{align*}
$$

Since $\mathcal{U}=\left\{\vec{u}_{1}, \vec{u}_{2}, \ldots, \vec{u}_{n}\right\}$ is a family of $S_{m}$-matching vectors, we have that $\left\langle\vec{u}_{i}, \vec{u}_{i}\right\rangle_{m}=0$ for each $i \in$ $[1, n]$ and $\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}=s_{i j} \in S_{m} \subseteq Z_{m} \backslash\{0\}$ for each $i, j \in[1, n]$ such that $i \neq j$, and from the definition of $S_{m}$-decoding polynomial $P(x)=a_{0}+a_{1} x^{b_{1}}+\cdots+a_{k-1} x^{b_{k-1}}$, we have that $P\left(\gamma^{\left\langle\vec{u}_{i}, \vec{u}_{i}\right\rangle_{m}}\right)=P(1)=1$ for each $i \in[1, n]$ and $P\left(\gamma^{\left\langle\vec{u}_{i}, \vec{u}_{j}\right\rangle_{m}}\right)=P\left(\gamma^{s_{i j}}\right)=0$ for each $i, j \in[1, n]$ such that $i \neq j$.

Thus it follows from (5) that $D_{i}\left(C\left(\vec{e}_{i}\right)\right)=P\left(\gamma^{\left\langle\vec{u}_{i}, \vec{u}_{i}\right\rangle_{m}}\right)=P(1)=1$ for each $i \in[1, n]$, and it follows from (6]) that $D_{i}\left(C\left(\vec{e}_{j}\right)\right)=\gamma^{-\left\langle\vec{u}_{i}, \vec{v}\right\rangle_{m}} \cdot \gamma^{\left\langle\vec{u}_{j}, \vec{v}\right\rangle_{m}} \cdot P\left(\gamma^{s_{i j}}\right)=0$ for each $i, j \in[1, n]$ such that $i \neq j$.
