Abstract. Recently formulated integrable theory of quantum transport [Osipov and Kanzieper, Phys. Rev. Lett. 101, 176804 (2008)] is extended to describe sample-to-sample fluctuations of the noise power in chaotic cavities with broken time-reversal symmetry. Concentrating on the universal transport regime, we determine dependence of the noise power cumulants on the temperature, applied bias voltage, and the number of propagating modes in the leads. Intrinsic connection between statistics of thermal to shot noise crossover and statistics of Landauer conductance is revealed and briefly discussed.

#### 1. Introduction: Thermal versus shot noise

The charge transfer through a phase-coherent cavity exhibiting chaotic classical dynamics is a random process influenced by discreteness of the electron charge e and the quantum nature of electrons (Blanter and Büttiker 2000, Imry 2002, Martin 2005). Fluctuations of charge transmitted during a fixed time interval or, equivalently, fluctuations  $\delta I(t)$  of current around its mean are quantified by the noise power

$$\mathcal{P} = 2 \int_{-\infty}^{+\infty} dt \left\langle \delta I(t+t_0) \delta I(t_0) \right\rangle_{t_0}, \qquad (1.1)$$

where the brackets  $\langle \cdots \rangle_{t_0}$  indicate the time averaging.

At temperatures  $\theta = k_B T$  which are much larger than a bias voltage v = eV applied to the cavity  $(\theta \gg v)$ , the current fluctuations are dominated by the equilibrium thermal noise, also known as Johnson-Nyquist noise. Caused by fluctuating occupation numbers in a flow of carriers injected into cavity from electronic reservoirs, thermal noise extends over all frequencies up to the quantum limit  $\theta/h$ . In the absence of electron-electron interactions, its power at zero bias voltage (v = 0) is related to the scattering matrix  $\delta$  of the system composed of the cavity and the leads (Khlus 1987, Lesovik 1989, Büttiker 1990, Martin and Landauer 1992, Büttiker 1992):

$$\mathcal{P}_{\text{th}}(\theta) = 4\theta \, G_0 \, \text{tr}(\mathcal{C}_1 \mathcal{S} \mathcal{C}_2 \mathcal{S}^{\dagger}). \tag{1.2}$$

Here,  $G_0 = e^2/h$  is the conductance quantum. The projection matrices  $\mathcal{C}_{1,2}$  encode the information about particular cavity-lead geometry and will be specified later on.

In the opposite limit of low temperatures ( $\theta \ll v$ ), the current fluctuations are still significant even though the flow of incident electrons is essentially noiseless. In this temperature regime, nonequilibrium current fluctuations (known as a *shot noise*) exist because of (i) the granularity of the electron charge e and (ii) the stochastic nature of electron scattering inside the cavity which splits the electron wave into two or more partial waves leaving the cavity through different exits. It is this "uncertainty of not knowing where the electron came from and where it will go to" (Oberholzer  $et\ al\ 2002$ ) that makes the transmitted charge to fluctuate. At zero temperature, the scattering matrix approach brings the shot noise power in the form

$$\mathcal{P}_{\text{shot}}(v) = 2v G_0 \left[ \text{tr}(\mathcal{C}_1 \mathcal{S} \mathcal{C}_2 \mathcal{S}^{\dagger}) - \text{tr}(\mathcal{C}_1 \mathcal{S} \mathcal{C}_2 \mathcal{S}^{\dagger})^2 \right]. \tag{1.3}$$

At finite temperatures, both sources of noise are operative, the total noise  $\mathcal{P}(\theta, v)$  being a complicated function of temperature and bias voltage ‡:

$$\mathcal{P}(\theta, \upsilon) = 4\theta G_0 \left( \operatorname{tr}(\mathcal{C}_1 \mathcal{S} \mathcal{C}_2 \mathcal{S}^{\dagger})^2 + \frac{\upsilon}{2\theta} \operatorname{coth}\left(\frac{\upsilon}{2\theta}\right) \left[ \operatorname{tr}(\mathcal{C}_1 \mathcal{S} \mathcal{C}_2 \mathcal{S}^{\dagger}) - \operatorname{tr}(\mathcal{C}_1 \mathcal{S} \mathcal{C}_2 \mathcal{S}^{\dagger})^2 \right] \right). \tag{1.4}$$

Equation (1.4) suggests that the crossover from thermal noise  $\mathcal{P}_{\text{th}}(\theta) = \mathcal{P}(\theta, 0)$  to shot noise  $\mathcal{P}_{\text{shot}}(v) = \mathcal{P}(0, v)$  depends in a sensitive way on scattering properties of the cavity and the leads incorporated in the scattering matrix  $\mathcal{S}$ . Since chaotic scattering of electrons inside the cavity induces fluctuations of  $\mathcal{S}$ -matrix (Blümel and Smilansky 1990), the noise power  $\mathcal{P}(\theta, v)$  fluctuates, too.

So far, the thermal to shot noise crossover has only been studied at the level of average noise power. For the two-terminal scattering geometry comprised of the cavity attached to outside reservoirs (kept at temperature  $\theta$ ) via two leads supporting  $N_{\rm L}$ 

 $<sup>\</sup>ddagger$  Equation (1.4) disregards the low-frequency 1/f noise that can efficiently be filtered out in experiments.

and  $N_{\rm R}$  propagating modes, respectively, the average noise power equals (Blanter and Sukhorukov 2000, Oberholzer *et al* 2001, Savin and Sommers 2006)

$$\langle \mathcal{P}(\theta, \upsilon) \rangle_{\mathcal{S}} = \langle \mathcal{P}_{\text{th}} \rangle_{\mathcal{S}} \left[ 1 + \frac{N_{\text{L}} N_{\text{R}}}{(N_{\text{L}} + N_{\text{R}})^2 - 1} f_{\beta} \right],$$
 (1.5)

where

$$\langle \mathcal{P}_{\rm th} \rangle_{\mathcal{S}} = 4\theta \, G_0 \frac{N_{\rm L} N_{\rm R}}{N_{\rm L} + N_{\rm R}} \tag{1.6}$$

is the average equilibrium thermal noise power, and the thermodynamic function

$$f_{\beta} = \beta \coth \beta - 1 \tag{1.7}$$

depends on the ratio  $\beta = v/2\theta$  between the bias voltage v and the temperature  $\theta$ . Equations (1.5) and (1.6) hold for cavities with broken time reversal symmetry §. Derived for the universal transport regime (Beenakker 1997, Richter and Sieber 2002, Müller et~al~2007) emerging in the limit  $\tau_{\rm D} \gg \tau_{\rm E}$  (Agam et~al~2000), where  $\tau_{\rm D}$  is the average electron dwell time and  $\tau_{\rm E}$  is the Ehrenfest time (the time scale where quantum effects set in), the above prediction has been confirmed in a remarkable series of experiments (Oberholzer et~al~2001, Cronet~al~2001, Oberholzer et~al~2002).

In this paper, we examine *statistics* of the thermal to shot noise crossover. The latter, contained in the distribution function of the noise power  $\mathcal{P}(\theta, v)$  or, equivalently, in its *cumulants*  $\langle\!\langle \mathcal{P}^{\ell} \rangle\!\rangle$ , can effectively be described within the framework of integrable theory of quantum transport formulated by Osipov and Kanzieper (2008). Let us stress that recent experimental studies (Flindt *et al* 2009) of quantum noise fluctuations in nanoscale conductors (which concentrated on detection of higher cumulants of noise) suggest that testing our predictions may be feasible within the current limits of nanotechnology.

# 2. Integrable theory of noise power fluctuations

In what follows, we consider chaotic cavities with broken time-reversal symmetry which are probed, via ballistic point contacts, by two (left and right) leads; the leads supporting  $N_{\rm L}$  and  $N_{\rm R}$  propagating modes, respectively, are further coupled to external reservoirs kept at the temperature  $\theta$ . This scattering geometry corresponds to the projection matrices  $\mathcal{C}_{1,2}$  of the form

$$\mathcal{C}_1 = \begin{pmatrix} \mathbb{1}_{N_{\mathrm{L}}} & 0\\ 0 & 0_{N_{\mathrm{R}}} \end{pmatrix}, \quad \mathcal{C}_2 = \begin{pmatrix} 0_{N_{\mathrm{L}}} & 0\\ 0 & \mathbb{1}_{N_{\mathrm{R}}} \end{pmatrix}, \tag{2.1}$$

see Eqs. (1.2) - (1.4).

#### 2.1. Joint cumulants of Landauer conductance and noise power

The starting point of our analysis is the *joint* cumulant generating function (JCGF)

$$\mathcal{F}_n(z, w) = \langle \exp(-z G/G_0) \exp(-w \mathcal{P}/\mathcal{P}_0) \rangle_{\mathcal{S} \in \text{CUE}(N)}$$
 (2.2)

of the Landauer conductance  $G = G_0 \operatorname{tr}(\mathcal{C}_1 \mathcal{S} \mathcal{C}_2 \mathcal{S}^{\dagger})$  and the noise power  $\mathcal{P}(\theta, v)$  measured in the units of  $G_0 = e^2/h$  and  $\mathcal{P}_0 = 4\theta G_0$ , respectively. The joint dimensionless cumulants

$$\kappa_{\ell,m} = \langle \langle (G/G_0)^{\ell} (\mathcal{P}/\mathcal{P}_0)^m \rangle \rangle \tag{2.3}$$

 $\S$  The two can readily be extended to other symmetry classes, see Savin and Sommers (2006).

can be extracted from the expansion

$$\log \mathcal{F}_n(z, w) = \sum_{\ell, m=0}^{\infty} (-1)^{\ell+m} \frac{z^{\ell} w^m}{\ell! \, m!} \, \kappa_{\ell, m}, \tag{2.4}$$

where  $\kappa_{0,0} \equiv 0$ . In both Eqs. (2.2) and (2.4), the subscript n stands for  $n = \min(N_{\rm L}, N_{\rm R})$ , and  $N = N_{\rm L} + N_{\rm R}$  is the total number of propagating modes (channels) in the leads. The notation  $S \in {\rm CUE}(N)$  indicates that averaging runs over scattering matrices S drawn from the Dyson circular unitary ensemble (Blümel and Smilansky 1990, Mello and Baranger 1999, Mehta 2004). The latter is microscopically justified (Lewenkopf and Weidenmüller 1991, Brouwer 1995) in the universal transport regime we are confined to.

To perform the averaging in Eq. (2.2) in a most economic way, we employ a polar decomposition (Hua 1963, Baranger and Mello 1994, Forrester 2006) of S-matrix. Bringing into play a set of n transmission eigenvalues  $\mathbf{T} = (T_1, \dots, T_n) \in (0, 1)^n$  distributed in accordance with the joint probability density function

$$P_n(T) = c_n^{-1} \Delta_n^2(T) \prod_{j=1}^n T_j^{\nu}, \tag{2.5}$$

this decomposition highlights Landauer's idea of viewing conductance as transmission,

$$G(T) = G_0 \sum_{j=1}^{n} T_j. (2.6)$$

Simultaneously, it reduces the expression for noise power [Eq. (1.4)] down to

$$\mathcal{P}(\mathbf{T}) = \mathcal{P}_0 \left( \sum_{j=1}^n T_j + f_\beta \sum_{j=1}^n T_j (1 - T_j) \right). \tag{2.7}$$

The parameter  $\nu$  in Eq. (2.5) is a measure of asymmetry between the leads,  $\nu = |N_{\rm L} - N_{\rm R}|$ , the notation  $\Delta_n(T)$  stands for the Vandermonde determinant  $\Delta_n(T) = \prod_{j < k} (T_k - T_j)$ , whilst  $c_n$  is a normalisation constant. As the result, we are left with the JCGF in the form

$$\mathcal{F}_n(z,w) = c_n^{-1} \int_{(0,1)^n} \prod_{i=1}^n dT_i \, T_j^{\nu} \, \Gamma_{z,w}(T_i) \, \Delta_n^2(\mathbf{T}), \tag{2.8}$$

where

$$\Gamma_{z,w}(T) = \exp\left[-(z+w)T - w f_{\beta} T(1-T)\right].$$
 (2.9)

Although the above matrix integral representation of the JCGF  $\mathcal{F}_n(z, w)$  is by far more complicated than the one appearing in the integrable theory of conductance fluctuations (Osipov and Kanzieper 2008),

$$\mathcal{F}_n(z,0) = \langle \exp(-zG/G_0) \rangle_{\mathcal{S} \in \text{CUE}(N)} = c_n^{-1} \int_{(0,1)^n} \prod_{j=1}^n dT_j \, T_j^{\nu} \, e^{-zT_j} \, \Delta_n^2(\boldsymbol{T}), \qquad (2.10)$$

it can still be treated nonperturbatively, much in line with the formalism used in the exact approach to zero-dimensional replica sigma models (Kanzieper 2002, Kanzieper 2005, Osipov and Kanzieper 2007, Kanzieper 2009).

#### 2.2. The $\tau$ function theory of the joint cumulant generating function

The "deform-and-study" approach (Morozov 1994, Adler et al 1995, Adler and van Moerbeke 2001) borrowed from the theory of integrable systems is central to the nonperturbative calculation of  $\mathcal{F}_n(z,w)$ . In the present context, the main idea of the method consists of "embedding"  $\mathcal{F}_n(z,w)$  into a more general theory of the  $\tau$  function

$$\tau_n(\mathbf{t}; z, w) = \frac{1}{n!} \int_{(0,1)^n} \prod_{j=1}^n dT_j \, T_j^{\nu} \, \Gamma_{z,w}(T_j) \, e^{V(\mathbf{t}; T_j)} \Delta_n^2(\mathbf{T})$$
 (2.11)

which possesses the infinite-dimensional parameter space  $\mathbf{t} = (t_1, t_2, \ldots)$  arising as the result of the  $\mathbf{t}$  deformation

$$V(t;T) = \sum_{k=1}^{\infty} t_k T^k. \tag{2.12}$$

Studying an evolution of the  $\tau$  function in the extended (n, t, z, w) space allows us to identify various nonlinear differential hierarchical relations. A projection of these relations onto the hyperplane t = 0,

$$\mathcal{F}_n(z,w) = \frac{n!}{c_n} \tau_n(t;z,w) \Big|_{t=0}, \tag{2.13}$$

generates, among others, a closed nonlinear differential equation for the JCGF  $\mathcal{F}_n(z,w)$ . It is this equation [Eq. (2.24)] that will further supply the cumulants of noise power.

The two key ingredients of the exact theory of  $\tau$  functions are (i) the bilinear identity (Date *et al* 1983) and (ii) the (linear) Virasoro constraints (Mironov and Morozov 1990).

## 2.2.1. Bilinear identity and Kadomtsev-Petviashvili equation

The bilinear identity encodes an infinite set of hierarchically structured nonlinear differential equations in the variables  $\mathbf{t} = (t_1, t_2, \ldots)$ . For the model introduced in Eq. (2.11), the bilinear identity reads (Adler *et al* 1995, Tu *et al* 1996):

$$\oint_{\mathcal{C}_{\infty}} dz \, e^{a \, v(\mathbf{t} - \mathbf{t}'; z)} \tau_n(\mathbf{t} - [\mathbf{z}^{-1}]) \, \frac{\tau_{m+1}(\mathbf{t}' + [\mathbf{z}^{-1}])}{z^{m+1-n}}$$

$$= \oint_{\mathcal{C}_{\infty}} dz \, e^{(a-1) \, v(\mathbf{t} - \mathbf{t}'; z)} \tau_m(\mathbf{t}' - [\mathbf{z}^{-1}]) \frac{\tau_{n+1}(\mathbf{t} + [\mathbf{z}^{-1}])}{z^{n+1-m}}. \tag{2.14}$$

Here,  $a \in \mathbb{R}$  is a free parameter; the integration contour  $\mathcal{C}_{\infty}$  encompasses the point  $z = \infty$ ; the notation  $t \pm [z^{-1}]$  stands for the infinite set of parameters  $\{t_j \pm z^{-j}/j\}$ ; for brevity, both z and w were dropped from the arguments of  $\tau$  functions.

Being expanded in terms of t'-t and a, Eq. (2.14) generates a variety of integrable hierarchies (Osipov and Kanzieper 2009). One of them is the Kadomtsev-Petviashvili (KP) hierarchy. Its first nontrivial member,

$$\left(\frac{\partial^4}{\partial t_1^4} + 3\frac{\partial^2}{\partial t_2^2} - 4\frac{\partial^2}{\partial t_1 \partial t_3}\right) \log \tau_n(\boldsymbol{t}; z, w) + 6\left(\frac{\partial^2}{\partial t_1^2} \log \tau_n(\boldsymbol{t}; z, w)\right)^2 = 0$$
(2.15)

is of primary importance since its projection onto  $\mathbf{t} = \mathbf{0}$  [Eq. (2.13)] gives rise to a nonlinear differential equation for the JCGF  $\mathcal{F}_n(z, w)$ . The resulting equation will further be used to determine the noise power cumulants we are aimed at.

#### 2.2.2. Virasoro constraints

Since we are interested in deriving a differential equation for  $\mathcal{F}_n(z, w)$  in terms of the derivatives over variables z and w, we have to seek an additional block of the theory that would make a link between  $t_j$ -derivatives in Eq. (2.15) taken at t = 0 and the derivatives over w and z. This missing block is the *Virasoro constraints* which reflect the invariance of the  $\tau$  function [Eq. (2.11)] under a change of the integration variables.

In the present context, it is useful to demand the invariance under the set of transformations

$$T_j \to \tilde{T}_j + \epsilon \, \tilde{T}_j^{q+1}(\tilde{T}_j - 1), \quad q \ge 0.$$
 (2.16)

Employing by now a standard procedure (Mironov and Morozov 1990, Adler and van Moerbeke 1995), one readily checks that the transformation (2.16) induces Virasoro constraints in the form

$$[\hat{L}_{q+1}(t) - \hat{L}_q(t)]\tau_n(t; z, w) = 0, \quad q \ge 0,$$
 (2.17)

where a set of differential operators

$$\hat{L}_{q}(t) = \hat{\mathcal{L}}_{q}(t) + 2f_{\beta} w \frac{\partial}{\partial t_{q+2}} - [z + (1 + f_{\beta}) w] \frac{\partial}{\partial t_{q+1}} + \nu \frac{\partial}{\partial t_{q}}$$
(2.18)

involves the Virasoro operators

$$\hat{\mathcal{L}}_q(t) = \sum_{j=1}^{\infty} j t_j \frac{\partial}{\partial t_{q+j}} + \sum_{j=0}^{q} \frac{\partial^2}{\partial t_j \partial t_{q-j}},$$
(2.19)

satisfying the Virasoro algebra

$$[\hat{\mathcal{L}}_p, \hat{\mathcal{L}}_q] = (p-q)\hat{\mathcal{L}}_{p+q}, \quad p, q \ge -1.$$
 (2.20)

In Eqs. (2.18) and (2.19), the convention  $\partial/\partial t_0 \equiv n$  is assumed.

# 2.2.3. Nonlinear differential equation for $\mathfrak{F}_n(z,w)$

To derive a differential equation for the JCGF  $\mathcal{F}_n(z, w)$ , one has to project the first KP equation Eq. (2.15) onto the hyperplane t = 0. Spotting the identities  $(f_{\beta} > 0)$ 

$$\frac{\partial}{\partial t_1} \tau_n(t; z, w) = -\frac{\partial}{\partial z} \tau_n(t; z, w), \qquad (2.21)$$

$$f_{\beta} \frac{\partial}{\partial t_2} \tau_n(\mathbf{t}; z, w) = \frac{\partial}{\partial w} \tau_n(\mathbf{t}; z, w) - (1 + f_{\beta}) \frac{\partial}{\partial z} \tau_n(\mathbf{t}; z, w), \qquad (2.22)$$

we combine Eqs. (2.15) with the Virasoro constraints Eq. (2.17) taken at q = 0,

$$\left[ \sum_{j=1}^{\infty} j t_j \left( \frac{\partial}{\partial t_{j+1}} - \frac{\partial}{\partial t_j} \right) + 2 f_{\beta} w \left( \frac{\partial}{\partial t_3} - \frac{\partial}{\partial t_2} \right) \right] \\
- \left[ z + (1 + f_{\beta}) w \right] \left( \frac{\partial}{\partial t_2} - \frac{\partial}{\partial t_1} \right) + (N_{\rm L} + N_{\rm R}) \frac{\partial}{\partial t_1} - N_{\rm L} N_{\rm R} \right] \tau_n(\mathbf{t}; z, w) = 0, \quad (2.23)$$

to derive:

$$\left[ w f_{\beta}^{2} \frac{\partial^{4}}{\partial z^{4}} + \left[ 2(N_{L} + N_{R}) f_{\beta} - 2z + w \left( 1 - f_{\beta}^{2} \right) \right] \frac{\partial^{2}}{\partial z^{2}} + 2(z - 2w) \frac{\partial^{2}}{\partial z \partial w} + 3w \frac{\partial^{2}}{\partial w^{2}} + 2\left( \frac{\partial}{\partial w} - \frac{\partial}{\partial z} \right) \right] \log \mathcal{F}_{n}(z, w) + 6w f_{\beta}^{2} \left( \frac{\partial^{2}}{\partial z^{2}} \log \mathcal{F}_{n}(z, w) \right)^{2} = 0. \quad (2.24)$$

Owing to Eq. (2.4), this nonlinear equation considered *together* with the equation for  $\mathcal{F}_n(z,0)$  contains all the information about joint cumulants of the Landauer conductance and the noise power. The latter equation, written in terms of

$$\sigma_n(z) = N_{\rm L} N_{\rm R} + z \frac{\partial}{\partial z} \log \mathcal{F}_n(z, 0),$$
 (2.25)

reads (Osipov and Kanzieper 2008):

$$z^{2} \frac{\partial^{3}}{\partial z^{3}} \sigma_{n}(z) + z \frac{\partial^{2}}{\partial z^{2}} \sigma_{n}(z) + 6z \left(\frac{\partial}{\partial z} \sigma_{n}(z)\right)^{2} - 4\sigma_{n} \frac{\partial}{\partial z} \sigma_{n}(z)$$
$$-\left[\left(z - (N_{L} + N_{R})\right)^{2} - 4N_{L} N_{R}\right] \frac{\partial}{\partial z} \sigma_{n}(z) - (N_{L} + N_{R} - z)\sigma_{n}(z) = 0. \quad (2.26)$$

This can be recognised as the Chazy form (Chazy 1911, Cosgrove and Scoufis 1993) of the fifth Painlevé transcendent

$$\left(z\frac{\partial^{2}}{\partial z^{2}}\sigma_{n}(z)\right)^{2} - \left[\sigma_{n}(z) + 2\left(\frac{\partial}{\partial z}\sigma_{n}(z)\right)^{2} + \left(N_{L} + N_{R} - z\right)\frac{\partial}{\partial z}\sigma_{n}(z)\right]^{2} + 4\left(\frac{\partial}{\partial z}\sigma_{n}(z)\right)^{2}\left(N_{L} + \frac{\partial}{\partial z}\sigma_{n}(z)\right)\left(N_{R} + \frac{\partial}{\partial z}\sigma_{n}(z)\right) = 0$$
(2.27)

written in the Jimbo-MIwa-Okamoto form (Jimbo et al 1980, Okamoto 1987). For completeness, we have included a detailed derivation of Eq. (2.26) into Appendix A.

### 2.3. Recurrence solution for joint cumulants

Combined with the cumulant expansion Eq. (2.4), the differential equation Eq. (2.24) furnishes the nonlinear recurrence for the joint dimensionless cumulants  $\kappa_{\ell,m}$  of conductance and noise power  $(\ell, m \ge 0)$ :

$$m \left[ f_{\beta}^{2} \kappa_{\ell+4,m-1} + (1 - f_{\beta}^{2}) \kappa_{\ell+2,m-1} \right] - 2 \left( N_{L} + N_{R} \right) f_{\beta} \kappa_{\ell+2,m}$$

$$-2 \left( \ell + 2m + 1 \right) \kappa_{\ell+1,m} + \left( 2\ell + 3m + 2 \right) \kappa_{\ell,m+1}$$

$$+ 6m f_{\beta}^{2} \sum_{i=0}^{m-1} {m-1 \choose i} \sum_{j=0}^{\ell} {\ell \choose j} \kappa_{j+2,i} \kappa_{\ell-j+2,m-i-1} = 0.$$
(2.28)

To resolve it, one must know the boundary conditions whose rôle is played by cumulants  $\kappa_{\ell,0} = \langle (G/G_0)^{\ell} \rangle$  of the dimensionless Landauer conductance. These have been nonperturbatively calculated in our previous publication (Osipov and Kanzieper 2008). Indeed, given the mean conductance

$$\kappa_{1,0} = \frac{N_{\rm L} N_{\rm R}}{N_{\rm L} + N_{\rm R}} \tag{2.29}$$

and its variance

$$\kappa_{2,0} = \frac{\kappa_{1,0}^2}{(N_{\rm L} + N_{\rm R})^2 - 1},\tag{2.30}$$

the higher order cumulants  $\kappa_{\ell,0}$ 's are determined by the one-dimensional recurrence  $\|[(N_{\rm L}+N_{\rm R})^2-\ell^2](\ell+1)\kappa_{\ell+1,0}+(N_{\rm L}+N_{\rm R})(2\ell-1)\ell\kappa_{\ell,0}$ 

$$+\ell(\ell-1)(\ell-2)\kappa_{\ell-1,0} - 2\sum_{j=0}^{\ell-1} (3j+1)(j-\ell)^2 \binom{\ell}{j} \kappa_{j+1,0} \kappa_{\ell-j,0} = 0.$$
 (2.31)

Equations (2.28) and (2.31) represent the main result of our study ¶. They provide a nonperturbative description of the noise power fluctuations in the crossover region between the thermal and the shot noise (Savin, Sommers and Wieczorek 2008) regimes (as discussed in the Introduction) by relating the temperature ( $\theta$ ) and bias-voltage (v) dependent cumulants of the noise power to those of the Landauer conductance.

Undoubtedly, the very existence of the above nontrivial relation (which emphasises a fundamental rôle played by Landauer conductance in transport problems) must be well rooted in the mathematical formalism and also have a good physics reason. As far as the former point is concerned, we wish to stress that a naïve attempt to build a theory for the generating function  $\mathcal{F}_n(0, w)$  of solely noise power cumulants faces an unsurmountable obstacle: the KP equation [Eq. (2.15)] and appropriate Virasoro constraints [Eq. (2.17) at z=0] cannot be resolved jointly in the hyperplane t=0. This justifies the starting point [Eq. (2.2)] of our analysis. The physics arguments behind the peculiar structure of our solution are yet to be found.

#### 2.4. Noise power cumulants in the crossover regime

Some computational effort is needed to read off explicit formulae for the noise power cumulants from Eqs. (2.28) and (2.31). Below we provide expressions for two families of joint cumulants expressed in terms of dimensionless cumulants  $\kappa_{\ell,0} = \langle (G/G_0)^{\ell} \rangle$  of the Landauer conductance.

• Mean noise power

$$\langle \langle \mathcal{P} \rangle \rangle = 4\theta G_0 \left[ N f_\beta \, \kappa_{2,0} + \kappa_{1,0} \right] \tag{2.32}$$

 $\parallel$  Equations (2.29), (2.30) and (2.31) follow from the cumulant expansion

$$\log \mathcal{F}_n(z,0) = \sum_{\ell=1}^{\infty} (-1)^{\ell} \frac{z^{\ell}}{\ell!} \kappa_{\ell,0},$$

see Eqs. (2.4) and (2.10), substituted into Eq. (2.27). Successive iterations of Eq. (2.31) yield the cumulants  $\kappa_{\ell,0}$  of Landauer conductance in the form

$$\kappa_{\ell,0} = \frac{(\ell-1)!}{\prod_{j=1}^{\ell-1} (N^2 - j^2)} p_{\ell}(\kappa_{1,0}),$$

where the first few polynomials  $p_{\ell}(\kappa)$  are:

$$\begin{aligned} p_1(\kappa) &= \kappa, \\ p_2(\kappa) &= \kappa^2, \\ p_3(\kappa) &= 4\kappa^3 - N\kappa^2, \\ p_4(\kappa) &= 12\left(2 - \frac{1}{N^2 - 1}\right)\kappa^4 - 10N\kappa^3 + (N^2 + 1)\kappa^2. \end{aligned}$$

Here,  $N = N_{\rm L} + N_{\rm R}$ .

¶ Notice that Eq. (15) in the paper by Osipov and Kanzieper (2008) contains typos. The correct formula is given by Eq. (2.31)

is generated by the lowest order member  $(\ell, m) = (0, 0)$  of the recurrence Eq. (2.28). Being in concert with the known expression Eqs. (1.5) and (1.6), this result is a particular case of a more general formula

$$\kappa_{\ell,1} = \kappa_{\ell+1,0} + N \frac{f_{\beta}}{\ell+1} \, \kappa_{\ell+2,0}. \tag{2.33}$$

• Noise power variance,

$$\langle\!\langle \mathcal{P}^2 \rangle\!\rangle = (4\theta G_0)^2 \left[ \left( \frac{2}{3} N^2 - 1 \right) \frac{f_\beta^2}{5} \kappa_{4,0} + N f_\beta \kappa_{3,0} + \left( 1 + \frac{f_\beta^2}{5} \right) \kappa_{2,0} - \frac{6}{5} f_\beta^2 \kappa_{2,0}^2 \right], \tag{2.34}$$

is supplied by the  $(\ell, m) = (0, 1)$  member of the recurrence. Its generalisation reads:

$$\kappa_{\ell,2} = \left(\frac{2N^2}{\ell+3} - 1\right) \frac{f_{\beta}^2}{2\ell+5} \kappa_{\ell+4,0} + 2N \frac{f_{\beta}}{\ell+2} \kappa_{\ell+3,0} + \left(1 + \frac{f_{\beta}^2}{2\ell+5}\right) \kappa_{\ell+2,0} \\
-6 \frac{f_{\beta}^2}{2\ell+5} \sum_{i=0}^{\ell} {\ell \choose j} \kappa_{j+2,0} \kappa_{\ell+2-j,0}.$$
(2.35)

Here and above,  $N = N_{\rm L} + N_{\rm R}$ .

The noise power cumulants  $\langle\langle \mathcal{P}^{\ell} \rangle\rangle$  of higher order  $(\ell \geq 3)$  can be calculated in the same manner albeit explicit expressions become increasingly cumbersome. Varying therein the parameters  $(\theta, v)$  from  $(\theta, 0)$  to (0, v), one observes a smooth crossover between the thermal and the shot noise regime.

# 2.5. Large-n analysis of joint cumulants: Symmetric leads

The nonpeturbative solution Eq. (2.28) and (2.31) has a drawback: it does not provide much desired *explicit* dependence of conductance and/or noise power cumulants  $\kappa_{\ell,m}$  on parameters of the scattering system. To probe such a dependence, we turn to the large-n limit of the recurrence Eq. (2.28). In what follows, the asymmetry parameter  $\nu$  will be set to zero.

Under the latter assumption ( $\nu = 0$ ), the joint cumulants  $\kappa_{\ell,m}$  are solutions to the recurrence equation ( $\ell, m \ge 0$ )

$$m \left[ f_{\beta}^{2} \kappa_{\ell+4,m-1} + (1 - f_{\beta}^{2}) \kappa_{\ell+2,m-1} \right] - 4n f_{\beta} \kappa_{\ell+2,m}$$

$$-2 (\ell + 2m + 1) \kappa_{\ell+1,m} + (2\ell + 3m + 2) \kappa_{\ell,m+1}$$

$$+ 6m f_{\beta}^{2} \sum_{i=0}^{m-1} {m-1 \choose i} \sum_{i=0}^{\ell} {\ell \choose j} \kappa_{j+2,i} \kappa_{\ell-j+2,m-i-1} = 0$$

$$(2.36)$$

which must be supplemented by yet another recurrence  $(\ell \geq 2)$ 

$$(4n^2 - \ell^2)(\ell+1)\kappa_{\ell+1,0} + 2n(2\ell-1)\ell\kappa_{\ell,0}$$

$$+\ell(\ell-1)(\ell-2)\kappa_{\ell-1,0} - 2\sum_{j=0}^{\ell-1} (3j+1)(j-\ell)^2 \binom{\ell}{j} \kappa_{j+1,0} \kappa_{\ell-j,0} = 0$$
 (2.37)

that brings, in turn, a set of initial conditions  $\kappa_{\ell,0}$  to Eq. (2.36).

#### 2.5.1. Cumulants of Landauer conductance

It is instructive to start with the asymptotic analysis of Eq. (2.37). In case of symmetric leads, the conductance cumulants of odd order vanish  $^+$ ,  $\kappa_{2\ell+1,0} \equiv 0$  for all  $\ell \geq 1$  albeit  $\kappa_{1,0} = n/2$ . As the result, one is left with the recurrence equation for the cumulants  $\kappa_{2\ell,0}$  of even order ( $\ell \geq 1$ )

$$[4n^{2} - (2\ell+1)^{2}](\ell+1)\kappa_{2\ell+2,0} + \ell(4\ell^{2} - 1)\kappa_{2\ell,0}$$

$$-8\sum_{j=0}^{\ell-1} (3j+2)(j-\ell)^{2} {2\ell+1 \choose 2j+1} \kappa_{2j+2,0} \kappa_{2\ell-2j,0} = 0$$
(2.38)

subject to the initial condition [Eq. (2.30)]

$$\kappa_{2,0} = \frac{n^2}{4(4n^2 - 1)} = \frac{1}{16} \sum_{\sigma=0}^{\infty} \frac{1}{(4n^2)^{\sigma}}.$$
 (2.39)

Since, in the limit of a large number of propagating modes  $(n \gg 1)$ , the conductance distribution is expected to roughly follow the Gaussian law (Politzer 1989) with the mean  $\kappa_{1,0}^{(G)} = n/2$  and the variance  $\kappa_{2,0}^{(G)} = 1/16$  [see Eqs. (2.29) and (2.30)], it is natural to seek a large-n solution to Eq. (2.38) in the form  $(j \ge 1)$ 

$$\kappa_{2\ell,0} = \frac{1}{16} \delta_{\ell,1} + \delta \kappa_{2\ell,0},\tag{2.40}$$

where  $\delta \kappa_{2\ell,0}$  (with  $\ell \geq 2$ ) account for deviations from the Gaussian distribution. Putting forward the large-n ansatz

$$\delta \kappa_{2\ell,0} = \frac{1}{n^{2\ell}} \sum_{\sigma=0}^{\infty} \frac{a_{2\ell}(2\sigma)}{n^{2\sigma}}, \quad \ell \ge 1, \tag{2.41}$$

where [see Eq. (2.39)]

$$a_2(2\sigma) = \frac{1}{2^{2\sigma+4}},\tag{2.42}$$

we further substitute it into Eq. (2.38) to derive:

$$\frac{a_{2\ell+2}(0)}{a_{2\ell}(0)} = \frac{1}{2^4} \frac{(2\ell+1)!}{(2\ell-1)!}, \quad \ell \ge 2, \tag{2.43}$$

and

$$\frac{a_4(0)}{a_2(2)} = \frac{3!}{2^4}. (2.44)$$

Hence.

$$a_{2\ell}(0) = \frac{1}{4} \frac{(2\ell - 1)!}{4^{2\ell}}. (2.45)$$

Taken together with Eq. (2.42), this yields the leading term in the 1/n expansion [Eq. (2.41)] for conductance cumulants:

$$\delta \kappa_{2\ell} \simeq \frac{1}{4} \frac{(2\ell - 1)!}{(4n)^{2\ell}}.$$
 (2.46)

The higher order corrections to Eq. (2.46) can be obtained in a regular way.

<sup>&</sup>lt;sup>+</sup> At the formal level, this is direct consequence of the identity  $\mathcal{F}_n(z,0) = e^{-nz}\mathcal{F}_n(-z,0)$  holding as soon as  $\nu = 0$ , see Eq. (2.10).

#### 2.5.2. Dependence of the noise power cumulants on temperature and bias voltage

Similarly to the previous subsection, we start an asymptotic analysis of the recurrence Eq. (2.36) with singling out the large-n Gaussian part:

$$\kappa_{\ell,m} = \frac{n}{2} \left[ \delta_{\ell,1} \delta_{m,0} + \left( 1 + \frac{f_{\beta}}{4} \right) \delta_{\ell,0} \delta_{m,1} \right] 
+ \frac{1}{16} \left[ \delta_{\ell,1} \delta_{m,1} + \delta_{\ell,2} \delta_{m,0} + \left( 1 + \frac{f_{\beta}^2}{8} \right) \delta_{\ell,0} \delta_{m,2} \right] + \delta \kappa_{\ell,m}.$$
(2.47)

The Gaussian part was read off from Eqs. (2.33) and (2.35); the term  $\delta \kappa_{\ell,m}$  accommodates non-Gaussian corrections to the joint cumulants of Landauer conductance and the noise power. Their large-n behavior can be studied within the 1/n ansatz

$$\delta \kappa_{\ell,m} = \frac{1}{n^{\ell+m}} \sum_{\sigma=0}^{\infty} \frac{a_{\ell,m}(\sigma)}{n^{\sigma}},\tag{2.48}$$

where  $a_{1,0}(\sigma) = 0$ . Substitution of Eqs. (2.47) and (2.48) into the two-dimensional recurrence Eq. (2.36) brings the recurrence equation  $(\ell + m > 0)$ 

$$m\left(1 - \frac{f_{\beta}^{2}}{4}\right) a_{\ell+2,m-1}(0) - 4f_{\beta}a_{\ell+2,m}(0)$$
$$-2(\ell+1+2m)a_{\ell+1,m}(0) + (2\ell+2+3m)a_{\ell,m+1}(0) = 0$$
(2.49)

for the expansion coefficients  $a_{\ell,m}(0)$  appearing in Eq. (2.48). The (unique) solution of Eq. (2.49), subject to the boundary condition

$$a_{\ell,0}(0) = \frac{(\ell-1)!}{2^{2\ell+3}} \left[ 1 + (-1)^{\ell} \right]$$
 (2.50)

derived in Sec. 2.5.1 [see Eq. (2.45)], reads  $(\ell + m > 0)$ :

$$a_{\ell,m}(0) = \frac{(\ell+m-1)!}{2^{2(\ell+m)+3}} \left[ \left( \frac{f_{\beta}}{2} + 1 \right)^m + (-1)^{\ell} \left( \frac{f_{\beta}}{2} - 1 \right)^m \right]. \tag{2.51}$$

Combined with Eq. (2.48), it yields the leading term in the 1/n expansion for joint cumulants of Landauer conductance and the noise power:

$$\delta \kappa_{\ell,m} \simeq \frac{1}{8} \frac{(\ell+m-1)!}{(4n)^{\ell+m}} \left[ \left( \frac{f_{\beta}}{2} + 1 \right)^m + (-1)^{\ell} \left( \frac{f_{\beta}}{2} - 1 \right)^m \right].$$
 (2.52)

Equations (2.47) and (2.52) are the central result of this Section.

In particular, it brings an the following large-n expression for the cumulants of noise power in case of symmetric leads:

$$\langle\!\langle \mathcal{P}^{\ell} \rangle\!\rangle \simeq (G_0 \theta)^{\ell} \left[ 2n \left( 1 + \frac{f_{\beta}}{4} \right) \delta_{\ell,1} + \left( 1 + \frac{f_{\beta}^2}{8} \right) \delta_{\ell,2} + \frac{(\ell - 1)!}{8n^{\ell}} \left[ \left( \frac{f_{\beta}}{2} - 1 \right)^{\ell} + \left( \frac{f_{\beta}}{2} + 1 \right)^{\ell} \right] \right].$$

$$(2.53)$$

Explicit dependence of the noise power cumulants on both the temperature  $\theta$  and the bias voltage v enters through a single function  $f_{\beta}$  [see Eq. (1.7)] that depends on the ratio  $\beta = v/2\theta$ . Based on Eq. (2.53), it can further be shown that small but nonvanishing cumulants of the third and higher order are responsible for long exponential tails in the otherwise Gaussian distribution of the noise power (compare with Vivo, Majumdar and Bohigas 2008).

#### 3. Conclusions

In summary, we have presented an advanced formulation of the recently proposed integrable theory of quantum transport (Osipov and Kanzieper 2008) to study statistics of noise power fluctuations in a chaotic cavity with broken time-reversal symmetry in the crossover regime  $(\theta,0) \to (0,v)$  between thermal and shot noise. By relating the cumulants of noise power to those of the Landauer conductance, we determined dependence of the noise power cumulants (as well as of joint cumulants of Landauer conductance and the noise power) on the bias voltage v, temperature  $\theta$ , and the number of channels  $N_{\rm L,R}$  in the leads attached to a cavity through ballistic point contacts.

We are confident that ideas of integrability combined with the scattering matrix approach are able to provide a nonperturbative description of many more transport phenomena in chaotic cavities. Quantum transport in cavities with losses (Doron, Smilansky and Frenkel 1991, Beenakker and Brouwer 2001, Simon and Moustakas 2006) and non-ideal leads (Brouwer 1995) are just two examples of chaotic scattering systems whose detailed study is much called for.

Note added.—Recently, we learnt about the paper by Khoruzhenko et al (2009) where an alternative approach was developed to describe statistics of conductance and shot-noise power in chaotic cavities with and without time-reversal symmetry. Possibly triggered by the earlier paper by Novaes (2008), these authors combine a theory of the Selberg integral with the theory of symmetric functions to evaluate the (joint) moments of Landauer conductance and the shot-noise power in terms of series over all partitions of the moment's order. In particular, Khoruzhenko et al (2009) confirm our large-n formulae Eqs. (2.46) and (2.53) at zero temperature.

# Appendix

# A. Cumulant generating function for the Landauer conductance and the fifth Painlevé transcendent

Relation to a gap formation probability.—The "simplest" (albeit not operative) way to observe that the conductance cumulant generating function  $\mathcal{F}_n(z,0)$  [Eq. (2.10)] can be expressed in terms of Painlevé V is to spot that  $\mathcal{F}_n(z,0)$  is essentially the gap formation probability within the interval  $(z,+\infty)$  in the spectrum of an  $n \times n$  Laguerre unitary ensemble. Indeed, the transformation of integration variables  $\lambda_j = zT_j$  in Eq. (2.10) yields

$$\mathcal{F}_n(z,0) = c_n^{-1} z^{-n(n+\nu)} \int_{(0,z)^n} \prod_{j=1}^n d\lambda_j \lambda_j^{\nu} e^{-\lambda_j} \, \Delta_n^2(\lambda). \tag{A.1}$$

A nonperturbative evaluation of the above n-fold integral is readily available (Tracy and Widom 1994, Forrester and Witte 2002) eventually resulting in the following Painlevé V representation (Osipov and Kanzieper 2008):

$$\mathcal{F}_n(z,0) = \exp\left(\int_0^z dt \frac{\sigma_n(t) - n(n+\nu)}{t}\right). \tag{A.2}$$

Here,  $\sigma_n(t)$  satisfies the Jimbo-Miwa-Okamoto form of the Painlevé V equation (Jimbo et al 1980, Okamoto 1987):

$$(t\sigma_n'')^2 + [\sigma_n - t\sigma_n' + 2(\sigma_n')^2 + (2n + \nu)\sigma_n']^2 + 4(\sigma_n')^2(\sigma_n' + n)(\sigma_n' + n + \nu) = 0 \quad (A.3)$$

subject to the boundary condition  $\sigma_{\rm V}(t\to 0)\simeq n(n+\nu)$ . Keeping in mind the parameterisation  $n=\min(N_{\rm L},N_{\rm L})$  and  $\nu=|N_{\rm L}-N_{\rm R}|$ , one concludes that Eq. (A.3) is equivalent to Eq. (2.27) announced in Sec. 2.2.3.

Direct evaluation of  $\mathfrak{F}_n(z,0)$ .—To directly evaluate  $\mathfrak{F}_n(z,0)$  defined by Eq. (2.10), we introduce the associated  $\tau$  function

$$\tau_n(\mathbf{t}; z) = \frac{1}{n!} \int_{(0,1)^n} \prod_{j=1}^n dT_j \, T_j^{\nu} \, e^{-zT_j + V(\mathbf{t}; T_j)} \Delta_n^2(\mathbf{T})$$
(A.4)

such that

$$\mathcal{F}_n(z,0) = \frac{n!}{c_n} \tau_n(t;z) \Big|_{t=0}, \tag{A.5}$$

and make use of the KP equation Eq. (2.15),

$$\left(\frac{\partial^4}{\partial t_1^4} + 3\frac{\partial^2}{\partial t_2^2} - 4\frac{\partial^2}{\partial t_1 \partial t_3}\right) \log \tau_n(t;z) + 6\left(\frac{\partial^2}{\partial t_1^2} \log \tau_n(t;z)\right)^2 = 0,$$
(A.6)

supplemented by the Virasoro constraints \*

$$[\hat{L}_{q+1}(t) - \hat{L}_q(t)]\tau_n(t;z) = 0, \quad q \ge 0,$$
 (A.7)

where a set of differential operators

$$\hat{L}_{q}(t) = \hat{\mathcal{L}}_{q}(t) - z \frac{\partial}{\partial t_{q+1}} + \nu \frac{\partial}{\partial t_{q}}$$
(A.8)

involves the Virasoro operators Eq. (2.19) [the convention  $\partial/\partial t_0 \equiv n$  is assumed].

In order to project the KP equation Eq. (A.6) onto  $\mathbf{t} = \mathbf{0}$ , we need only two Virasoro constraints labeled by q = 0,

$$\left[\sum_{j=1}^{\infty} j t_j \left(\frac{\partial}{\partial t_{j+1}} - \frac{\partial}{\partial t_j}\right) - z \frac{\partial}{\partial t_2} + (2n + \nu + z) \frac{\partial}{\partial t_1}\right] \log \tau_n(\boldsymbol{t}; z) = n(n + \nu), \quad (A.9)$$

and q=1

$$\left[ \sum_{j=1}^{\infty} j t_j \left( \frac{\partial}{\partial t_{j+2}} - \frac{\partial}{\partial t_{j+1}} \right) - z \frac{\partial}{\partial t_3} + (2n + \nu + z) \frac{\partial}{\partial t_2} - (2n + \nu) \frac{\partial}{\partial t_1} + \frac{\partial^2}{\partial t_1^2} \right] \log \tau_n(\mathbf{t}; z) + \left( \frac{\partial}{\partial t_1} \log \tau_n(\mathbf{t}; z) \right)^2 = 0.$$
(A.10)

<sup>\*</sup> Equations (A.7) and (A.8) readily follow from Eqs. (2.17) and (2.18) upon setting  $f_{\beta}=0$  and w=0.

References 14

Here

$$\frac{\partial}{\partial t_1} \tau_n(t; z) = -\frac{\partial}{\partial z} \tau_n(t; z). \tag{A.11}$$

Lengthy but straightforward manipulations with Eqs. (A.9) and (A.10) as well as with their derivatives over  $t_1$  and  $t_2$  projected onto  $\mathbf{t} = \mathbf{0}$  result in Eqs. (2.25) and (2.26).
