Abstract. This article formalizes an abstraction of input/output relations, based on parameterized zonotopes, which we call affine sets. We describe the abstract transfer functions and prove their correctness, which allows the generation of accurate numerical invariants. Other applications range from compositional reasoning to proofs of user-defined complex invariants and test case generation.

1 Introduction

We present in this paper an abstract domain based on affine arithmetic [4] to bound the values of variables in numerical programs, with a real number semantics. Affine arithmetic can be conceived as describing particular polytopes, called zonotopes [19], which are bounded and center-symmetric. But it does so by explicitly parametrizing the points, as affine combinations of symbolic variables, called noise symbols. This parametrization keeps, in an implicit manner, the affine correlations between values of program variables, by sharing some of these noise symbols. It is tempting then to attribute a meaning to these noise symbols, so that the abstract elements we are considering are no longer merely polytopes, but have a functional interpretation, due to their particular parametrization: we define abstract elements as tuples of affine forms, which we call affine sets. They define a sound abstraction of relations that hold between the current values of the variables, for each control point, and the inputs of a program. The interests of abstracting input/output relations are well-known [6], we mention but a few: more precise and scalable interprocedural abstractions, proofs of complex invariants (involving relations between inputs and outputs), sensitivity analysis and test case generation as exemplified in [7].

An abstract domain relying on such affine forms has been described in [8,11,13], but these descriptions miss complete formalization, and over-approximate the input/output relations more than necessary. In this paper, we extend this preliminary work by presenting a natural framework for this domain, with a partial order relation that allows Kleene like iteration for accurately solving fixed point equations. In particular, a partial order that is now global to the abstract state, and no longer defined independently on each variable, allows to use relations also between the special noise symbols created by taking an upper bound of two affine forms. Our results are illustrated with sample computations and geometric interpretations.

A preliminary version of this abstract domain, extended to analyse the uncertainty due to floating-point computations, is used in practice in a real industrial-size static analyser - FLUCTUAT - whose applications have been described in [7,14]. A preliminary version of this domain, dedicated to the analysis of computations in real numbers, is also implemented as an abstract domain - Taylor1+ [8] - of the open-source library APRON [17].

Related work Apart from the work of the authors already mentioned, that uses zonotopes in static analysis, a large amount of work has been carried out mostly for reachability analysis in hybrid systems using zonotopes, see for instance [9]. One common feature with our work is the fact that zonotopic methods prove to be precise and fast. But in general, in hybrid systems analysis, no union operator is defined, whereas it is an essential feature of our work. Also, the methods used are purely geometrical: no information is kept concerning input/output relationships, e.g. as witnessed by the methods used for computing intersections [10]. Zonotopes have also been used in imaging, in collision detection for instance, see [16], where purely geometrical joins have been defined.

Recent work in static analysis by abstract interpretation for input/output relations abstraction and modular analyses can be found in [6], where an example is given in particular using polyhedra. In [5], it is shown that some classical analyses (e.g. Mycroft's strictness analysis) are input/output relational analyses (also called dependence-sensitive analyses). Applications of abstractions of input/output relations have been developed, in particular for points-to alias analysis, using summary functions, see for instance [3].

Contents In Section 2, we quickly introduce the principles of affine arithmetic, and show the interest of a domain with explicit parametrization of zonotopes, compared to its geometric counterpart, through simple examples. Then in Section 3, we state properties of affine sets. Introducing a matrix representation, we make the link between the affine sets and their zonotope concretisation. We then introduce perturbed affine sets, that will allow us to define a partially ordered structure. Starting with a thorough explanation of the intuition at Section 4.1, we then describe the partial order relation in Section 4.3, the monotonic abstract transfer functions in Section 4.4, and the join operator in Section 4.5. For intrinsic reasons, our abstract domain does not have least upper bounds, but minimal upper bounds. We show in Section 4.6 that a form of bounded-completeness holds that allows Kleene-like iteration for solving fixed point equations. By lack of space, we do not demonstrate here the behaviour of our abstract domain on fixed-point computations, but results on preliminary versions of our domain are described in [8,13].

2 Abstracting input/output relations with affine arithmetic

Affine arithmetic Affine arithmetic is an extension of interval arithmetic on affine forms, first introduced in [4], that takes into account affine correlations

between variables. An *affine form* is a formal sum over a set of *noise symbols* ε_i

$$\hat{x} \stackrel{def}{=} \alpha_0^x + \sum_{i=1}^n \alpha_i^x \varepsilon_i,$$

with $\alpha_i^x \in \mathbb{R}$ for all i . Each noise symbol ε_i stands for an independent component of the total uncertainty on the quantity \hat{x} , its value is unknown but bounded in $[-1,1]$; the corresponding coefficient α_i^x is a known real value, which gives the magnitude of that component. The same noise symbol can be shared by several quantities, indicating correlations among them. These noise symbols can not only model uncertainty in data or parameters, but also uncertainty coming from computation.

The semantics of affine operations is straightforward, non affine operations are linearized : we refer the reader to [11,13] for more details on the semantics for static analysis.

Introductory examples Consider the simple interprocedural program :

```

float main() {
    float x ∈ [-1,1];
    return f(x)-x;
}

float f(float x) {
    float y;
    if (x >= 0) y = x + 1;
    else y = x - 1;
    return y; }

```

In order to analyse this program precisely, we need to infer the relation between the input and output of function f , since the `main` function subtracts the input of f from its output. We will show in Section 4.1 that our method gives an accurate representation of such input/output relations, at low cost, easily proving here that `main` returns a number between -1 and 1. We will also show that even tight geometric representations of the image of f on $[a,b]$ may fail to prove this.

Another interest of our method is to allow compositional abstractions for interprocedural calls [6], making our domain very scalable. For instance, the abstract value for the output of f , as found in Section 4.1, represents the fact that its value is the value of the input plus an unknown value in $[-1,1]$. In fact a little more might be found out, which would lay the basis for efficient disjunctive analyses, where we would find that the output of f is its input plus an unknown value in $\{-1,1\}$. This is left for future work. This compact representation can be used as an abstract *summary function* (akin to the ones of [3] or of [5]) for f which can then be reused without re-analysis for each calls to f . The complete discussion of this aspect is nevertheless outside the scope of this paper.

Last but not least, input/output relations that are dealt with by our method allow proofs of complex invariants, and test case generation at low cost. Consider for instance the following program, where g computes an approximation of the square root of x using a Taylor expansion of degree 2, centered at point 1:

```

float main() {
    float x ∈ [1,2], z, t;
    z = g(x);
    t = z*z-x;
    return t; }

float g(float x) {
    float y;
    y = 3/8.0+3/4.0*x-1/8.0*x*x
    return y;
}

```

With our semantics, we will find the following abstract value for x , z and t : $x = \frac{3}{2} + \frac{1}{2}\varepsilon_1$, $z = \frac{19}{16} + \frac{3}{16}\varepsilon_1 - \frac{1}{64}\varepsilon_2$ and $t = -\frac{567}{8192} - \frac{7}{128}\varepsilon_1 - \frac{19}{512}\varepsilon_2 - \frac{169}{8192}\varepsilon_3$. This proves that z is within $[\frac{63}{64}, \frac{89}{64}] \sim [0.984, 1.391]$ (real result is $[1, 1.375]$), and that t is within $[-\frac{93}{512}, \frac{329}{4196}] \sim [-0.182, 0.078]$ (real result is $[-0.066, 0]$). This means that we get a rather precise estimate of the quality of the algorithm that approximates the square root. Finally, examining the dependency of t on the noise symbol modelling the input, we see that $\varepsilon_1 = 1$, that is $x = 2$, is the most likely value for reaching the maximum of t , in absolute value. This input value is thus a good test case to maximize the algorithmic error between the approximation of square root and the real square root. Here it does indeed correspond to the worst case. These applications are detailed in [7], and stronger statements about test case generation can be found in [12], where a generalized form for abstract values is used for under-approximations.

3 Affine sets and zonotopes : notations and properties

In what follows, we introduce matrix notations to handle tuples of affine forms, which we call affine sets, and characterize the geometric concretisation of sets of values taken by these affine sets.

We note $\mathcal{M}(n, p)$ the space of matrices with n lines and p columns of real coefficients. An affine set expressing the set of values taken by p variables over n noise symbols ε_i , $1 \leq i \leq n$, can be represented by a matrix $A \in \mathcal{M}(n+1, p)$.

For example, consider the affine set

$$\hat{x} = 20 - 4\varepsilon_1 + 2\varepsilon_3 + 3\varepsilon_4 \quad (1)$$

$$\hat{y} = 10 - 2\varepsilon_1 + \varepsilon_2 - \varepsilon_4, \quad (2)$$

we have $n = 4$, $p = 2$ and ${}^tA = \begin{pmatrix} 20 & -4 & 0 & 2 & 3 \\ 10 & -2 & 1 & 0 & -1 \end{pmatrix}$. Two matrix multiplications will be of interest in what follows :

- Au , where $u \in \mathbb{R}^p$, represents a linear combination of our p variables, expressed on the ε_i basis,
- tAe , where $e \in \mathbb{R}^{n+1}$, $e_0 = 1$ and $\|e\|_\infty = \max_{0 \leq i \leq n} |e_i| \leq 1$, represents the vector of actual values that our p variables take for the particular values e_i for each of our ε_i noise variables. In this case, the additional symbol e_0 which is equal to 1, accounts for constant terms, as done for instance in the zone abstract domain [18].

We formally define the zonotopic concretisation of affine sets by :

Definition 1. Let an affine set with p variables over n noise symbols, defined by a matrix $A \in \mathcal{M}(n+1, p)$. Its concretisation is the zonotope

$$\gamma(A) = \{ {}^t A^t(1|e) \mid e \in \mathbb{R}^n, \|e\|_\infty \leq 1 \} \subseteq \mathbb{R}^p.$$

We call its linear concretisation the zonotope centered on 0

$$\gamma_{lin}(A) = \{ {}^t A e \mid e \in \mathbb{R}^{n+1}, \|e\|_\infty \leq 1 \} \subseteq \mathbb{R}^p.$$

For example, Figure 1 represents the concretization of the affine set defined by (1) and (2). It is a zonotope with center (20, 10) given by the vector of constant coefficients of the affine forms.

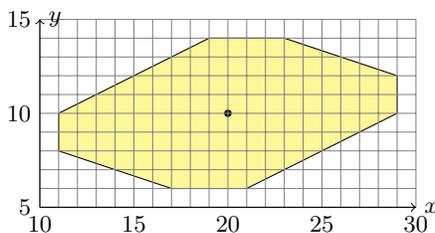

Fig. 1. Zonotope concretization $\gamma(A)$ of affine set $\{(1)-(2)\}$

Zonotopes are particular bounded convex polyhedra [19]. A way to characterize convex shapes is to consider support functions. For any direction $t \in \mathbb{R}^p$, let p_t the function which associates to all $x \in \mathbb{R}^p$, $p_t(x) = \langle t, x \rangle$ where $\langle \cdot, \cdot \rangle$ is the standard scalar product in \mathbb{R}^p , meaning that $p_t(x) = \sum_{i=1}^p t_i x_i$. Level-sets of support functions, i.e. sets defined by bounds on such functions characterize convex sets [1], and nicely characterize zonotopes centered on 0:

Lemma 1. Let S be a convex shape in \mathbb{R}^p . Then S can be characterized as the (possibly infinite) intersection $\bigcap_{t \in \mathbb{R}^p} B_t$ of half-spaces of the form

$$B_t = \{ x \in \mathbb{R}^p \mid p_t(x) \leq \sup_{y \in S} p_t(y) \}$$

In case S is a zonotope centered around 0, it has finitely many faces with normals t_i ($1 \leq i \leq k$), and this intersection is finite:

$$S = \bigcap_{1 \leq i \leq k} \left\{ x \in \mathbb{R}^p \mid |p_{t_i}(x)| \leq \sup_{y \in S} p_{t_i}(y) \right\}$$

Furthermore, there is an easy way to characterize the linear concretization $\gamma_{lin}(A)$ (see also [15]):

Lemma 2. Given a matrix $A \in \mathcal{M}(n+1, p)$, for all $t \in \mathbb{R}^p$, $\sup_{y \in \gamma_{lin}(A)} p_t(y) = \|At\|_1$, where $\|e\|_1 = \sum_{i=0}^n |e_i|$ is the ℓ_1 norm.

PROOF. First of all, $\gamma_{lin}(A)$ is the image of the unit disc for the L^∞ norm by tA as we noted in Definition 1. Therefore,

$$\sup_{\{y \in \gamma_{lin}(A)\}} p_t(y) = \sup_{\{e \in \mathbb{R}^{n+1}, \|e\|_\infty \leq 1\}} p_t({}^tAe)$$

We now have

$$\begin{aligned} p_t({}^tAe) &= \langle t, {}^tAe \rangle = \langle At, e \rangle = \sum_{i=0}^n \left(\sum_{j=1}^p a_{i,j} t_j \right) e_i \\ &\leq \sum_{i=0}^n \left| \sum_{j=1}^p a_{i,j} t_j \right| \|e\|_\infty = \|At\|_1 \|e\|_\infty \end{aligned}$$

This bound is reached for $e_i = \text{sign} \left(\sum_{j=1}^p a_{i,j} t_j \right)$, which is such that $\|e\|_\infty = 1$. \square

We illustrate Lemma 2 in Figure 2. Consider the matrix A' associated to affine set $\{(1)-(2)\}$ without its center. Its affine concretisation is the same zonotope as $\gamma(A)$ but centered on 0. For $l \in \mathbb{R}$, $t \in \mathbb{R}^p$, the (l, t) -level set corresponds to points on the hyperplane defined by : for $x \in \mathbb{R}^p$, $p_t(x) = \langle t, x \rangle = l$. This hyperplane is orthogonal to the line L_t going through 0, with direction t . It intersects L_t at a point $y = \lambda t$ such that $\|t\|_2^2 \lambda = l$. Given t a direction in \mathbb{R}^2 , the (l, t) -level set that intersects $\gamma_{lin}(A')$ with maximal value for l realizes $l = \sup_{\gamma_{lin}(A')} p_t(y) = \|A't\|_1$ by Lemma 2. We now take three vectors t such that $\|t\|_2 = 1$. For $t_1 = {}^t(1, 0)$, $\|A't_1\|_1 = 9$, we find the maximum of its concretisation on the x -axis to be 9. For $t_2 = {}^t(3/5, 4/5)$, $\|A't_2\|_1 = 7/5$, and $\gamma_{lin}(A') \subseteq H_{t_2}$, where H_{t_2} is the region (or band) between the line orthogonal to t_2 depicted as a blue dashed line and its symmetric with respect to zero. For $t_3 = {}^t(2/\sqrt{40}, 6/\sqrt{40})$ which is orthogonal to a face of the zonotope, $\|A't_3\|_1 = 3/4$ and $\gamma_{lin}(A') \subseteq H_{t_3}$, which is the band between the two parallel faces in green.

And indeed, for any matrix A , $\gamma_{lin}(A)$ is entirely described by providing the set of values $\|At\|_1$, where t varies among all directions in \mathbb{R}^p :

Lemma 3. *For matrices $X \in \mathcal{M}(n, p)$ and $Y \in \mathcal{M}(m, p)$, we have $\gamma_{lin}(X) \subseteq \gamma_{lin}(Y)$ if and only if $\|Xu\|_1 \leq \|Yu\|_1$ for all $u \in \mathbb{R}^p$.*

PROOF. Suppose first that $\|Xu\|_1 \leq \|Yu\|_1$ for all $u \in \mathbb{R}^p$. By first part of Lemma 1,

$$\gamma_{lin}(X) = \bigcap_{t \in \mathbb{R}^p} \{x \in \mathbb{R}^n \mid p_t(x) \in [\inf_{y \in \gamma(X)} p_t(y), \sup_{y \in \gamma(X)} p_t(y)]\}$$

with $\sup_{y \in \gamma(X)} p_t(y) = -\inf_{y \in \gamma(X)} p_t(y) = \|Xt\|_1$ by Lemma 2. Thus

$$\begin{aligned} \gamma_{lin}(X) &= \bigcap_{t \in \mathbb{R}^p} \{x \in \mathbb{R}^n \mid |p_t(x)| \leq \|Xt\|_1\} \\ &\subseteq \bigcap_{t \in \mathbb{R}^p} \{x \in \mathbb{R}^n \mid |p_t(x)| \leq \|Yt\|_1\} = \gamma_{lin}(Y). \end{aligned}$$

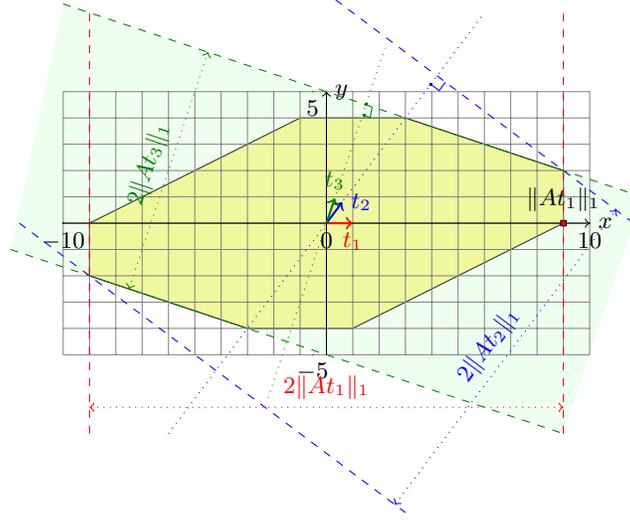

Fig. 2. Affine concretization $\gamma_{lin}(A')$ of affine set (1)-(2) without its center
 Conversely, suppose $\gamma_{lin}(X) \subseteq \gamma_{lin}(Y)$. Then

$$\|Xt\|_1 = \sup_{x \in \gamma_{lin}(X)} p_t(x) \leq \sup_{x \in \gamma_{lin}(Y)} p_t(x) = \|Yt\|_1.$$

□

4 Perturbed affine sets

4.1 Rationale

Let us get back to the program defining function f in Section 2. We introduce a noise symbol ε_1 to represent the range of values $[-1, 1]$ for x . Using for example the sub-optimal join operator described in Lemma 10 to come, the affine set for x and y at the end of the program will be $x = \varepsilon_1$, $y = \varepsilon_1 + \eta_1$, with a new (perturbation) noise symbol η_1 . The corresponding zonotope Z_1 is depicted in solid red in Figure 3.

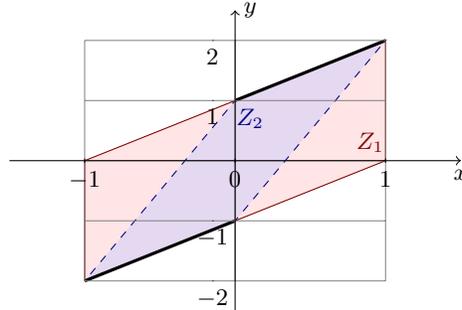

Fig. 3. Two abstractions for the result of example function f defined Section 2

Now, a better *geometrical* abstraction of the abstract value of (\mathbf{x}, \mathbf{y}) is the zonotope Z_2 depicted in dashed blue in Figure 3. Since $y = x + 1$ for positive x and $y = x - 1$ for negative x , we only have to include the two segments in solid dark in the smallest zonotope as possible. This is realized easily by a zonotope defined by the faces $x - y \in [-1, 1]$ and $y - 3x \in [-3, 3]$. Let us take a new symbol η_2 to represent $x - y$, and η_3 to represent $y - 3x$. This gives $x = -0.5\eta_2 - 0.5\eta_3$ and $y = -1.5\eta_2 - 0.5\eta_3$. Although the corresponding blue zonotope Z_2 is strictly included in the red zonotope Z_1 , so it is *geometrically* more precise, we lose relations to the input values. Indeed, symbols ε_i express dependencies to inputs of the program, whereas symbols η_i do not. Thus, computing \mathbf{y} minus the input of \mathbf{f} , as in the `main` function of the example, gives $-\varepsilon_1 - 1.5\eta_2 - 0.5\eta_3 \in [-3, 3]$. This range is far less precise than using the representation Z_1 , where we find that this difference is equal to $\eta_1 \in [-1, 1]$.

If we were not interested in input/output relations, a classical abstraction based on affine sets would be using the geometrical ordering on zonotopes. We would say that affine set X is less or equal than Y iff $\gamma(X) \subseteq \gamma(Y)$. For the sake of simplicity in the present discussion, suppose that $\gamma(X)$ and $\gamma(Y)$ are centered on 0. By Lemma 3, we would then ask for $\|Xt\|_1 \leq \|Yt\|_1$ for all $t \in \mathbb{R}^p$.

Now, being interested in input/output relations, we will keep the existing symbols used to express possible ranges of values of input variables (for instance, ε_1 defines the value of input variable \mathbf{x} in the example above), and which should have a very strict interpretation, as well as the noise symbols due to (non linear) arithmetic operations. We call them the *central* noise symbols (such as ε_1). And, to express uncertainty on these relations due to possibly different execution paths, we will add additional noise symbols which we call *perturbation* noise symbols (such as η_1 in the example above).

We now define an ordered structure using these two sets of noise symbols.

4.2 Definition

We thus consider *perturbed* affine sets X as Minkowski sums [1] of a *central* zonotope $\gamma(C^X)$ and of a *perturbation* zonotope (always centered on 0) $\gamma_{lin}(P^X)$:

Definition 2. We define a *perturbed affine set* X by the pair of matrices $(C^X, P^X) \in \mathcal{M}(n+1, p) \times \mathcal{M}(m, p)$. We call $C^X = (c_{ik}^X)_{0 \leq i \leq n, 1 \leq k \leq p}$ the *central matrix*, and $P^X = (p_{jk}^X)_{1 \leq j \leq m, 1 \leq k \leq p}$ the *perturbation matrix*.

The *perturbed affine form* $\pi_k(X) = c_{0k}^X + \sum_{i=1}^n c_{ik}^X \varepsilon_i + \sum_{j=1}^m p_{jk}^X \varepsilon_j^U$, where the ε_i are the *central noise symbols* and the ε_j^U the *perturbation or union noise symbols*, describes the k^{th} variable of X . We call $\gamma(C^X)$ the *central zonotope* and $\gamma_{lin}(P^X)$ the *perturbation zonotope*.

For instance Z_1 as defined in Section 4.1 is described by $C^1 = (1 \ 1)$, $P^1 = (0 \ 1)$ (first column corresponds to variable \mathbf{x} , second column, to \mathbf{y}). Z_2 is de-

scribed by $C^2 = (0 \ 0)$ (the line corresponding to ε_1) and $P^2 = \begin{pmatrix} -0.5 & -1.5 \\ -0.5 & -0.5 \end{pmatrix}$ (the first line corresponds to perturbation symbol η_2 , the second to η_3).

4.3 Ordered structure

Expressing X less or equal than Y on these perturbed affine sets with the geometrical order yields

$$\|C^X t\|_1 - \|C^Y t\|_1 \leq \|P^Y t\|_1 - \|P^X t\|_1, \forall t \in \mathbb{R}^p.$$

But many transformations that leave $\|C^X t\|_1$ and $\|C^Y t\|_1$ fixed for all t , and thus preserve that inequality, lose the intended meaning of the central noise symbols. We can fix this easily, by strengthening this preorder. Note that for all t , $\|C^X t\|_1 - \|C^Y t\|_1 \leq \|(C^X - C^Y)t\|_1$, so defining

$$X \leq Y \text{ iff } \|(C^X - C^Y)t\|_1 \leq \|P^Y t\|_1 - \|P^X t\|_1$$

should imply the geometrical ordering at least (as we will prove in Lemma 5). The good point is that no transformation on the central noise symbols is allowed any longer using this preorder (as the characterization of the equivalence relation generated by this preorder will show, see Lemma 4), keeping a strict interpretation of the noise symbols describing the values of the input variables, hence the input/output relations.

We now formalize and study this stronger order:

Definition 3. *Let $X = (C^X, P^X)$, $Y = (C^Y, P^Y)$ be two perturbed affine sets in $\mathcal{M}(n+1, p) \times \mathcal{M}(m, p)$. We say that $X \leq Y$ iff*

$$\sup_{u \in \mathbb{R}^p} (\|(C^Y - C^X)u\|_1 + \|P^X u\|_1 - \|P^Y u\|_1) \leq 0$$

Coming back to our example of Section 4.1, $\gamma(Z_2) \subseteq \gamma(Z_1)$ but $Z_2 \not\leq Z_1$. Take for instance $t = {}^t(1, 1)$. Then $\|(C^1 - C^2)t\|_1 + \|P^2 t\|_1 - \|P^1 t\|_1 = 2 + 3 - 1 = 4 > 0$.

Lemma 4. *The binary relation \leq of Definition 3 is a preorder. The equivalence relation generated by this preorder is $X \sim Y$ iff by definition $X \leq Y$ and $Y \leq X$. It can be characterized by $C^X = C^Y$ and $\gamma_{\text{in}}(P^X) = \gamma_{\text{in}}(P^Y)$ (geometrically speaking, as sets). We still denote \leq / \sim by \leq in the rest of the text.*

PROOF. Reflexivity of \leq is immediate. Suppose now $X \leq Y$ and $Y \leq Z$, then for all $u \in \mathbb{R}^p$:

$$\begin{aligned} \|(C^Y - C^X)u\|_1 &\leq \|P^Y u\|_1 - \|P^X u\|_1 \\ \|(C^Z - C^Y)u\|_1 &\leq \|P^Z u\|_1 - \|P^Y u\|_1 \end{aligned}$$

Using the triangular inequality, we get

$$\begin{aligned} \|(C^Z - C^X)u\|_1 &\leq \|(C^Z - C^Y)u\|_1 + \|(C^Y - C^X)u\|_1 \\ &\leq \|P^Z u\|_1 - \|P^Y u\|_1 + \|P^Y u\|_1 - \|P^X u\|_1 \\ &\leq \|P^Z u\|_1 - \|P^X u\|_1 \end{aligned}$$

implying $X \leq Z$, hence transitivity of \leq .

Finally, $X \leq Y$ and $Y \leq X$ imply that for all $u \in \mathbb{R}^p$, $\|(C^Y - C^X)u\|_1$ is less or equal than $\|P^Y u\|_1 - \|P^X u\|_1$ and is also less or equal than $\|P^X u\|_1 - \|P^Y u\|_1$. Hence $(C^Y - C^X)u = 0$ for all u , meaning $C^Y = C^X$ and $\|P^X u\|_1 = \|P^Y u\|_1$ for all u . By Lemma 3 this exactly means that $\gamma(P^X) = \gamma(P^Y)$. \square

Lemma 5. *Take $X = (C^X, P^X)$ and $Y = (C^Y, P^Y)$. Then $X \leq Y$ implies*

$$\gamma\left(\frac{C^X}{P^X}\right) \subseteq \gamma\left(\frac{C^Y}{P^Y}\right)$$

or said in a different manner: $\gamma(C^X) \oplus \gamma_{lin}(P^X) \subseteq \gamma(C^Y) \oplus \gamma_{lin}(P^Y)$ where \oplus denotes the Minkowski sum. Note that $X \leq Y$ implies $\gamma_{lin}(P^X) \subseteq \gamma_{lin}(P^Y)$.

PROOF. It is easy to prove that $\gamma_{lin}\left(\frac{C^X}{P^X}\right) \subseteq \gamma_{lin}\left(\frac{C^Y}{P^Y}\right)$ given that $X \leq Y$, using Lemma 3 and the triangular inequality for $\|\cdot\|_1$.

However, what we want is a little stronger. In order to derive it, we define, for all matrix A of dimension $(n+1) \times p$, a matrix \tilde{A} of dimension $(n+1) \times (p+1)$ by

$$\tilde{A} = \left(\begin{array}{c|c} 1 & \\ \hline 0 & A \\ \vdots & \\ 0 & \end{array} \right)$$

The interest of this transformation, is that the zonotopic concretisation $\gamma(A)$ is a particular face (which is the intersection with an hyperplane) of the 0-centered zonotope $\gamma_{lin}(\tilde{A})$:

$$\gamma(A) = \gamma_{lin}(\tilde{A}) \cap \{(1, x_1, \dots, x_p) \mid (x_1, \dots, x_p) \in \mathbb{R}^p\}. \quad (3)$$

We now prove $\gamma_{lin}\left(\frac{C^X}{P^X}\right) \subseteq \gamma_{lin}\left(\frac{C^Y}{P^Y}\right)$. For all $t = {}^t(t_0, \dots, t_p) \in \mathbb{R}^{p+1}$,

$$\left\| \left(\frac{C^X}{P^X}\right)t \right\|_1 - \left\| \left(\frac{C^Y}{P^Y}\right)t \right\|_1$$

$$\begin{aligned} &= \|\widetilde{C^X}t\|_1 - \|\widetilde{C^Y}t\|_1 + \|P^X t\|_1 - \|P^Y t\|_1 \\ &= |t_0 + \sum_{k=1}^p c_{0,k}^X t_k| - |t_0 + \sum_{k=1}^p c_{0,k}^Y t_k| + \|(c_{i,k}^X)_{1 \leq i \leq n, 1 \leq k \leq p} {}^t(t_1, \dots, t_p)\|_1 \\ &\quad - \|(c_{i,k}^Y)_{1 \leq i \leq n, 1 \leq k \leq p} {}^t(t_1, \dots, t_p)\|_1 + \|P^X t\|_1 - \|P^Y t\|_1 \\ &\leq | \sum_{k=1}^p c_{0,k}^X t_k - \sum_{k=1}^p c_{0,k}^Y t_k | + \|(c_{i,k}^X)_{1 \leq i \leq n, 1 \leq k \leq p} {}^t(t_1, \dots, t_p)\|_1 \\ &\quad - \|(c_{i,k}^Y)_{1 \leq i \leq n, 1 \leq k \leq p} {}^t(t_1, \dots, t_p)\|_1 + \|P^X t\|_1 - \|P^Y t\|_1 \\ &\leq \|(C^Y - C^X)t\|_1 + \|P^X t\|_1 - \|P^Y t\|_1 \leq 0 \end{aligned}$$

Hence by Lemma 3, $\gamma_{lin}\left(\frac{C^X}{P^X}\right) \subseteq \gamma_{lin}\left(\frac{C^Y}{P^Y}\right)$ which, by (3), implies the result. \square

The order we define is in fact essentially more complex than the inclusion ordering, while still being computable:

Lemma 6. *The partial order \leq is decidable, with a complexity bounded by a polynomial in p and an exponential in $n + m$.*

PROOF. The problem can be solved using $O(2^{(n+m)})$ linear programs. Let $X = (C^X, P^X)$, $Y = (C^Y, P^Y)$ be two perturbed affine sets in $\mathcal{M}(n+1, p) \times \mathcal{M}(m, p)$. We want to decide algorithmically whether $X \leq Y$ that is

$$\sup_{u \in \mathbb{R}^p} (\|(C^Y - C^X)u\|_1 + \|P^X u\|_1 - \|P^Y u\|_1) \leq 0$$

Looking at the proof of Lemma 2, we see that

$$\|Au\|_1 = \sup_{\{e \in \mathbb{R}^{n+1}, \|e\|_\infty \leq 1\}} \sum_{i=0}^n \left(\sum_{j=1}^p a_{i,j} u_j \right) e_i$$

and that this bound is reached for $e \in \mathbb{R}^{n+1}$ such that for all i , $e_i = 1$ or $e_i = -1$.

We therefore produce, for each $e \in \mathbb{R}^{n+1}$, $f \in \mathbb{R}^{m+1}$ and $g \in \mathbb{R}^{m+1}$, with, for all i , $e_i = 1$ or $e_i = -1$, $f_i = 1$ or $f_i = -1$, $g_i = 1$ or $g_i = -1$, the following linear program:

$$\sup_{u \in \mathbb{R}^p} \left(\sum_{i=0}^n \sum_{j=1}^p (c_{i,j}^Y - c_{i,j}^X) e_i u_j + \sum_{i=1}^m \sum_{j=1}^p p_{i,j}^X f_i u_j - \sum_{i=1}^m \sum_{j=1}^p p_{i,j}^Y g_i u_j \right)$$

subject to

$$\begin{aligned} \left(\sum_{j=1}^p (c_{i,j}^Y - c_{i,j}^X) u_j \right) e_i &\geq 0, \quad \forall 0 \leq i \leq n \\ \left(\sum_{j=1}^p p_{i,j}^X u_j \right) f_i &\geq 0, \quad \forall 1 \leq i \leq m \\ \left(\sum_{j=1}^p p_{i,j}^Y u_j \right) g_i &\geq 0, \quad \forall 1 \leq i \leq m \end{aligned}$$

that we solve using any linear program solver (with polynomial complexity). We then check for each problem that it is either not satisfiable or its supremum is negative or zero. \square

Hopefully, there is no need to use this general decision procedure in a static analyser by abstract interpretation. We refer the reader to the end of Section 4.6 for a discussion on this point.

4.4 Extension of affine arithmetic on perturbed affine forms

Interpretation of assignments and correctness issues We detail below the interpretation of arithmetic expressions, dealing first with affine assignments, that do not lose any precision. We use a very simple form for the multiplication. There are in fact more precise ways to compute assignments containing polynomial expressions. Firstly, the multiplication formula can be improved, see [8,11]. Secondly, when interpreting a non-linear assignment, it is better in practice to introduce new noise symbols for the entire expression, and not for every non linear elementary operation as we present here. But for sake of simplicity, we do not describe this here. Note also that we would need formally to prove that projections onto a subset of variables (change of scope), and renumbering of variables are monotonic operations, but these are easy checks and we omit them here. Note finally that the proofs of monotonicity of our transfer functions are not only convenient for getting fixpoints for our abstract semantics functionals. They are also necessary for proving the correctness of our approach. As already stated in [11,13], the correctness criterion we need relies on the property that whenever $X \leq Y$ are two perturbed affine sets, all future evaluations using expressions e give smaller concretisations starting with X than starting with Y , i.e. $\gamma(\llbracket e \rrbracket X) \subseteq \gamma(\llbracket e \rrbracket Y)$. This is proven easily as follows: as $\llbracket e \rrbracket$ is a composite of monotonic functions, $\llbracket e \rrbracket X \leq \llbracket e \rrbracket Y$. The conclusion holds because of Lemma 5.

Affine assignments We first define the assignment of a possibly unknown constant within bounds $a, b \in \mathbb{R}$ to a (new) variable, $x_{p+1} := [a, b]$:

Definition 4. Let $X = (C^X, P^X)$ be a perturbed affine set in $\mathcal{M}(n+1, p) \times \mathcal{M}(m, p)$ and $a, b \in \mathbb{R}$. We define $Z = \llbracket x_{p+1} = [a, b] \rrbracket X \in \mathcal{M}(n+2, p+1) \times \mathcal{M}(m, p+1)$ with :

- $c_{i,k}^Z = c_{i,k}^X$ for all $i = 0, \dots, n, k = 1, \dots, p$
- $c_{0,p+1}^Z = \frac{a+b}{2}$, $c_{i,p+1}^Z = 0$ for all $i = 1, \dots, n$ and $c_{n+1,p+1}^Z = \frac{|a-b|}{2}$
- $p_{j,k}^Z = p_{j,k}^X$ for all $j = 1, \dots, m, k = 1, \dots, p$
- $p_{j,p+1}^Z = 0$ for all $j = 1, \dots, m$

Or in block matrix form, $C^Z = \left(\begin{array}{c|c} C^X & \begin{array}{c} \frac{a+b}{2} \\ 0 \\ \dots \\ 0 \end{array} \\ \hline 0 & \frac{|a-b|}{2} \end{array} \right)$, $P^Z = \left(\begin{array}{c|c} P^X & \begin{array}{c} 0 \\ \dots \\ 0 \end{array} \end{array} \right)$

We carry on by addition, or more precisely, the operation interpreting the assignment $x_{p+1} := x_i + x_j$ and adding new variable x_{p+1} to the affine set:

Definition 5. Let $X = (C^X, P^X)$ be a perturbed affine set in $\mathcal{M}(n+1, p) \times \mathcal{M}(m, p)$. We define $Z = \llbracket x_{p+1} = x_i + x_j \rrbracket X = (C^Z, P^Z) \in \mathcal{M}(n+1, p+1) \times \mathcal{M}(m, p+1)$

$\mathcal{M}(m, p+1)$ by

$$C^Z = \left(C^X \left| \begin{array}{c} c_{0,i}^X + c_{0,j}^X \\ \dots \\ c_{n,i}^X + c_{n,j}^X \end{array} \right. \right) \text{ and } P^Z = \left(P^X \left| \begin{array}{c} p_{1,i}^X + p_{1,j}^X \\ \dots \\ p_{m,i}^X + p_{m,j}^X \end{array} \right. \right).$$

Finally, we give a meaning to the interpretation of assignments of the form $x_{p+1} := \lambda x_i$, for $\lambda \in \mathbb{R}$:

Definition 6. Let $X = (C^X, P^X)$ be a perturbed affine set in $\mathcal{M}(n+1, p) \times \mathcal{M}(m, p)$. We define $Z = \llbracket x_{p+1} = \lambda x_i \rrbracket X = (C^Z, P^Z) \in \mathcal{M}(n+1, p+1) \times \mathcal{M}(m, p+1)$ by

$$C^Z = \left(C^X \left| \begin{array}{c} \lambda c_{0,i}^X \\ \dots \\ \lambda c_{n,i}^X \end{array} \right. \right) \text{ and } P^Z = \left(P^X \left| \begin{array}{c} \lambda p_{1,i}^X \\ \dots \\ \lambda p_{m,i}^X \end{array} \right. \right).$$

We can prove the correctness of our abstract semantics:

Lemma 7. Operations $X \rightarrow \llbracket x_{p+1} = [a, b] \rrbracket X$, $X \rightarrow \llbracket x_{p+1} = x_i + x_j \rrbracket X$ and $X \rightarrow \llbracket x_{p+1} = \lambda x_i \rrbracket X$ are increasing over perturbed affine sets. Moreover these three operations do not introduce over-approximations.

PROOF. Suppose we are given two perturbed affine sets X and Y such that $X \leq Y$.

First, for constant assignments, we have, for all $t \in \mathbb{R}^{p+1}$:

$$\begin{aligned} \|(C^{\llbracket x_{p+1}=[a,b] \rrbracket X} - C^{\llbracket x_{p+1}=[a,b] \rrbracket Y})t\|_1 &= \|(C^X - C^Y)t\|_1 \\ &\leq \|P^Y t\|_1 - \|P^X t\|_1 \\ &\leq \|P^{\llbracket x_{p+1}=[a,b] \rrbracket Y} t\|_1 - \|P^{\llbracket x_{p+1}=[a,b] \rrbracket X} t\|_1 \end{aligned}$$

which shows monotonicity of $X \rightarrow \llbracket x_{p+1} = [a, b] \rrbracket X$ The concretisation of $\llbracket x_{p+1} = [a, b] \rrbracket X$ is obviously exact.

Now for addition of variables, we have, for all $t \in \mathbb{R}^{p+1}$:

$$\begin{aligned} \|(C^{\llbracket x_{p+1}=x_i+x_j \rrbracket X} - C^{\llbracket x_{p+1}=x_i+x_j \rrbracket Y})t\|_1 &= \\ &= \sum_{l=0}^n \left| \sum_{k=0}^{p+1} (c_{l,k}^{\llbracket x_{p+1}=x_i+x_j \rrbracket X} - c_{l,k}^{\llbracket x_{p+1}=x_i+x_j \rrbracket Y}) t_k \right| \\ &= \sum_{l=0}^n \left| \sum_{k=0}^p (c_{l,k}^X - c_{l,k}^Y) t_k + (c_{l,i}^X + c_{l,j}^X) t_{p+1} \right| \\ &= \|(C^X - C^Y)^t(t_1, \dots, t_i + t_{p+1}, \dots, t_j + t_{p+1}, \dots, t_p)\|_1 \\ &\leq \|P^Y t(t_1, \dots, t_i + t_{p+1}, \dots, t_j + t_{p+1}, \dots, t_p)\|_1 \\ &\quad - \|P^X t(t_1, \dots, t_i + t_{p+1}, \dots, t_j + t_{p+1}, \dots, t_p)\|_1 \\ &= \|P^{\llbracket x_{p+1}=x_i+x_j \rrbracket Y} t\|_1 - \|P^{\llbracket x_{p+1}=x_i+x_j \rrbracket X} t\|_1 \end{aligned}$$

which shows monotonicity of $X \rightarrow \llbracket x_{p+1} = x_i + x_j \rrbracket X$ The concretisation of $\llbracket x_{p+1} = x_i + x_j \rrbracket X$ is obviously exact.

And finally, we have, for all $t \in \mathbb{R}^{p+1}$:

$$\begin{aligned}
& \| (C^{\llbracket x_{p+1} = \lambda x_i \rrbracket X} - C^{\llbracket x_{p+1} = \lambda x_i \rrbracket Y}) t \|_1 = \\
& = \sum_{l=0}^n \left| \sum_{k=0}^{p+1} (c_{l,k}^{\llbracket x_{p+1} = \lambda x_i \rrbracket X} - c_{l,k}^{\llbracket x_{p+1} = \lambda x_i \rrbracket Y}) t_k \right| \\
& = \sum_{l=0}^n \left| \sum_{k=0}^p (c_{l,k}^X - c_{l,k}^Y) t_k + \lambda c_{l,p+1}^X t_{p+1} \right| \\
& = \| (C^X - C^Y)^t(t_1, \dots, t_i + \lambda t_{p+1}, \dots, t_p) \|_1 \\
& \leq \| P^Y t(t_1, \dots, t_i + \lambda t_{p+1}, \dots, t_p) \|_1 \\
& \quad - \| P^X t(t_1, \dots, t_i + \lambda t_{p+1}, \dots, t_p) \|_1 \\
& = \| P^{\llbracket x_{p+1} = \lambda x_i \rrbracket Y} t \|_1 - \| P^{\llbracket x_{p+1} = \lambda x_i \rrbracket X} t \|_1
\end{aligned}$$

which shows monotonicity of $X \rightarrow \llbracket x_{p+1} = \lambda x_i \rrbracket X$. The concretisation of $\llbracket x_{p+1} = \lambda x_i \rrbracket X$ is obviously exact. \square

Polynomial assignments The following operation defines the multiplication of variables x_i and x_j , appending the result to the perturbed affine set X . All polynomial assignments can be defined using this and the previous operations.

Definition 7. Let $X = (C^X, P^X)$ be a perturbed affine set in $\mathcal{M}(n+1, p) \times \mathcal{M}(m, p)$. We define $Z = (C^Z, P^Z) = \llbracket x_{p+1} = x_i \times x_j \rrbracket X \in \mathcal{M}(n+2, p+1) \times \mathcal{M}(m+1, p+1)$ by :

$$\begin{aligned}
& - c_{i,k}^z = c_{i,k}^x \text{ and } c_{n+1,k}^z = 0 \text{ for all } i = 0, \dots, n \text{ and } k = 1, \dots, p \\
& - c_{0,p+1}^z = c_{0,i}^x c_{0,j}^y \\
& - c_{l,p+1}^z = c_{0,i}^x c_{l,j}^y + c_{l,i}^x c_{0,j}^y \text{ for all } l = 1, \dots, n \\
& - c_{n+1,p+1}^z = \sum_{1 \leq r, l \leq n} | c_{r,i}^x c_{l,j}^y | \\
& - p_{l,k}^z = p_{l,k}^x, p_{m+1,k}^z = 0 \text{ and } p_{l,p+1}^z = 0, \text{ for all } l = 1, \dots, m \text{ and } k = 1, \dots, p \\
& - p_{m+1,p+1}^z = \sum_{1 \leq r, l \leq m} | p_{r,i}^x p_{l,j}^y | + \sum_{0 \leq r \leq n} | c_{r,i}^x p_{l,j}^y | + \sum_{0 \leq l \leq n} | p_{l,i}^x c_{r,j}^y |
\end{aligned}$$

Lemma 8. The operation $X \rightarrow \llbracket x_{p+1} = x_i \times x_j \rrbracket X$ is increasing, and has a concretisation which contains the set of points of the form (x_1, \dots, x_{p+1}) with $(x_1, \dots, x_p) \in \gamma(X)$ and $x_{p+1} = x_i x_j$.

PROOF. Let X and Y be two perturbed affine sets such that $X \leq Y$, and let $U = \llbracket x_{p+1} = x_i \times x_j \rrbracket X$ and $T = \llbracket x_{p+1} = x_i \times x_j \rrbracket Y$. We compute for all $t \in \mathbb{R}^{p+1}$:

$$\begin{aligned}
 \|(C^T - C^Z)t\|_1 &= \left| \sum_{l=1}^p (c_{0,l}^Y - c_{0,l}^X)t_l + (c_{0,i}^Y c_{0,j}^Y - c_{0,i}^X c_{0,j}^X) t_{p+1} \right| \\
 &\quad + \sum_{k=1}^n \left| \sum_{l=1}^p (c_{k,l}^Y - c_{k,l}^X)t_l \right. \\
 &\quad \left. + (c_{0,i}^Y c_{k,j}^Y + c_{k,i}^Y c_{0,j}^Y - c_{0,i}^X c_{k,j}^X - c_{k,i}^X c_{0,j}^X) \right| t_{p+1} \\
 &\quad + \left| \sum_{k=1}^n \sum_{l=1}^p (|c_{k,i}^Y c_{k,j}^Y| - |c_{k,i}^X c_{k,j}^X|) \right| t_{p+1} \\
 &\leq \left| \sum_{k=0}^n \sum_{l=1}^p (c_{k,l}^Y - c_{k,l}^X)t_l \right| \\
 &\quad + \left| ((c_{0,i}^Y - c_{0,i}^X)c_{0,j}^Y + c_{0,i}^X(c_{0,j}^Y - c_{0,j}^X)) t_{p+1} \right| \\
 &\quad + \sum_{k=1}^n \left| ((c_{k,j}^Y - c_{k,j}^X)c_{0,i}^X + c_{k,j}^Y(c_{0,i}^Y - c_{0,i}^X)) \right. \\
 &\quad \left. + (c_{k,i}^Y - c_{k,i}^X)c_{0,j}^Y + c_{k,i}^X(c_{0,j}^Y - c_{0,j}^X) \right| t_{p+1} \\
 &\quad + \left| \sum_{k=1}^n \sum_{l=1}^p (|c_{k,i}^Y| - |c_{k,i}^X|) |c_{l,j}^Y| \right. \\
 &\quad \left. + |c_{k,i}^X| (|c_{l,j}^Y| - |c_{l,j}^X|) \right| t_{p+1} \\
 &\leq \|P^Y t\|_1 - \|P^X t\|_1 \\
 &\quad + \left(\sum_{l=0}^n |c_{l,j}^Y| \right) \left(\sum_{k=0}^n |c_{k,i}^Y - c_{k,i}^X| \right) |t_{p+1}| \\
 &\quad + \left(\sum_{k=0}^n |c_{k,i}^X| \right) \left(\sum_{l=0}^n |c_{l,j}^Y - c_{l,j}^X| \right) |t_{p+1}|
 \end{aligned}$$

But $X \leq Y$ so $\pi_i(X) \leq \pi_i(Y)$ and $\pi_j(X) \leq \pi_j(Y)$. Therefore,

$$\left(\sum_{k=0}^n |c_{k,i}^X| \right) \left(\sum_{l=0}^n |c_{l,j}^Y - c_{l,j}^X| \right) \leq \|\pi_i(C^X)\|_1 (\|\pi_j(P^Y)\|_1 - \|\pi_j(P^X)\|_1)$$

and,

$$\left(\sum_{l=0}^n |c_{l,j}^Y| \right) \left(\sum_{k=0}^n |c_{k,i}^Y - c_{k,i}^X| \right) \leq \|\pi_j(C^Y)\|_1 (\|\pi_i(P^Y)\|_1 - \|\pi_i(P^X)\|_1)$$

Hence,

$$\begin{aligned}
 \|(C^T - C^Z)t\|_1 &\leq \|P^Y t\|_1 + \|\pi_i(C^X)\|_1 \|\pi_j(P^Y)\|_1 |t_{p+1}| \\
 &\quad + \|\pi_j(C^Y)\|_1 \|\pi_i(P^Y)\|_1 |t_{p+1}| \\
 &\quad - \|P^X t\|_1 - \|\pi_i(C^X)\|_1 \|\pi_j(P^X)\|_1 |t_{p+1}| \\
 &\quad - \|\pi_j(C^Y)\|_1 \|\pi_i(P^X)\|_1 |t_{p+1}| \\
 &\leq \|P^Y t\|_1 + (\|\pi_i(C^X - X^Y)\|_1 + \|\pi_i(C^Y)\|_1) \|\pi_j(P^Y)\|_1 |t_{p+1}| \\
 &\quad + \|\pi_j(C^Y)\|_1 \|\pi_i(P^Y)\|_1 |t_{p+1}| \\
 &\quad - \|P^X t\|_1 - \|\pi_i(C^X)\|_1 \|\pi_j(P^X)\|_1 |t_{p+1}| \\
 &\quad + (\|\pi_j(C^X - C^Y)\|_1 + \|\pi_j(C^X)\|_1) \|\pi_i(P^X)\|_1 |t_{p+1}| \\
 &\leq \|P^Y t\|_1 + (\|\pi_i(P^Y)\|_1 \|\pi_j(P^Y)\|_1 + \|\pi_i(C^Y)\|_1 \|\pi_j(P^Y)\|_1 \\
 &\quad + \|\pi_j(C^Y)\|_1 \|\pi_i(P^Y)\|_1) |t_{p+1}| \\
 &\quad - \|P^X t\|_1 + (\|\pi_i(P^X)\|_1 \|\pi_j(P^X)\|_1 - \|\pi_i(C^X)\|_1 \|\pi_j(P^X)\|_1 \\
 &\quad - \|\pi_j(C^X)\|_1 \|\pi_i(P^X)\|_1) |t_{p+1}|
 \end{aligned}$$

Hence the result, since precisely:

$$p_{m+1,p+1}^z = \sum_{1 \leq r, l \leq m} |p_{r,i}^x p_{l,j}^y| + \sum_{0 \leq r \leq n, 1 \leq l \leq m} |c_{r,i}^x p_{l,j}^y| + \sum_{0 \leq l \leq n, 1 \leq r \leq m} |p_{l,i}^x c_{r,j}^y|$$

is also equal to

$$\|\pi_i(P^X)\|_1 \|\pi_j(P^X)\|_1 + \|\pi_i(C^X)\|_1 \|\pi_j(P^X)\|_1 + \|\pi_j(C^X)\|_1 \|\pi_i(P^X)\|_1$$

Finally, the fact that the image of x_{p+1} contains all the products $x_i \times x_j$ is trivial. \square

4.5 The join operator

We first recall the definition of a minimal upper bound or *mub*:

Definition 8. Let \sqsubseteq be a partial order on a set X . We say that z is a mub of two elements x, y of X if and only if

- z is an upper bound of x and y , i.e. $x \sqsubseteq z$ and $y \sqsubseteq z$,
- for all z' upper bound of x and y , $z' \sqsubseteq z$ implies $z = z'$.

We give below an example of such mubs on perturbed affine sets.

Example 1. Consider

$$X = \begin{pmatrix} 1 + \varepsilon_1 \\ 1 + \varepsilon_1 \end{pmatrix} \quad Y = \begin{pmatrix} 1 + 2\varepsilon_1 \\ 1 + 2\varepsilon_1 \end{pmatrix} \quad Z = \begin{pmatrix} 1 + 1.5\varepsilon_1 + 0.5\eta_1 \\ 1 + 1.5\varepsilon_1 + 0.5\eta_1 \end{pmatrix}$$

Z is a mub for X and Y , given by a ‘‘midpoint’’ formula.

This gives us an idea on how to find, in $O((n+m)p)$ time, a mub in some cases, or a tight upper bound, in all cases:

Lemma 9. Let $X = (C^X, P^X)$ and $Y = (C^Y, P^Y)$ be two perturbed affine sets in $\mathcal{M}(n+1, p) \times \mathcal{M}(m, p)$. Upper bounds $Z = (C^Z, P^Z)$ of X and Y satisfy:

$$\forall t \in \mathbb{R}^p, \|P^Z t\|_1 \geq \frac{1}{2} (\|(C^Y - C^X)t\|_1 + \|P^X t\|_1 + \|P^Y t\|_1) \quad (4)$$

When $\gamma_{lin}(P^X) = \gamma_{lin}(P^Y)$, there exists a mub Z with P^Z satisfying (4) with equality; it is defined by $Z = (C^Z, P^Z) \in \mathcal{M}(n+1, p) \times \mathcal{M}(m+n+1, p)$ with:

- $c_{i,k}^Z = \frac{1}{2} (c_{i,k}^X + c_{i,k}^Y)$ for all $i = 0, \dots, n, k = 1, \dots, p$
- $p_{j+1,k}^Z = \frac{1}{2} (c_{j,k}^X - c_{j,k}^Y)$ for all $j = 0, \dots, n, k = 1, \dots, p$
- $p_{n+j+1,k}^Z = p_{j,k}^X$ for all $j = 1, \dots, m, k = 1, \dots, p$

PROOF. We begin by showing the following: let $X = (C^X, P^X)$ and $Y = (C^Y, P^Y)$ two perturbed affine sets in $\mathcal{M}(n+1, p) \times \mathcal{M}(m, p)$. Minimal upper bounds $Z = (C^Z, P^Z)$ of X and Y satisfy:

$$\forall t \in \mathbb{R}^p, \|P^Z t\|_1 \geq \frac{1}{2} (\|(C^Y - C^X)t\|_1 + \|P^X t\|_1 + \|P^Y t\|_1) \quad (5)$$

As $X \leq Z$ and $Y \leq Z$, we have, for all $t \in \mathbb{R}^p$:

$$\|(C^Z - C^X)t\|_1 \leq \|P^Z t\|_1 - \|P^X t\|_1 \quad (6)$$

$$\|(C^Z - C^Y)t\|_1 \leq \|P^Z t\|_1 - \|P^Y t\|_1 \quad (7)$$

So,

$$\begin{aligned} \|(C^Y - C^X)t\|_1 &\leq \|(C^Z - C^Y)t\|_1 + \|C^Z - C^X\|_1 \\ &\leq 2\|P^Z t\|_1 - \|P^X t\|_1 - \|P^Y t\|_1 \end{aligned}$$

Therefore we have inequality 5.

If ever we find $Z = (C^Z, P^Z)$ such that inequality 5 is in fact an equality, and such that Z is an upper bound of X and Y , then we are sure that Z is a mub. Since whenever we take another upper bound T of X and Y , T cannot possibly be strictly less than Z , for $\|P^Z t\|_1 - \|P^T t\|_1 \leq 0$ by inequality 5.

We notice that the equation on zonotope P^Z given by

$$\|P^Z t\|_1 = \frac{1}{2} (\|(C^Y - C^X)t\|_1 + \|P^Y t\|_1 + \|P^X t\|_1)$$

trivially realizing inequality 5 as an equality, can easily be solved by taking PZ as the Minkowski sum of zonotopes given by $C^Y - C^X$, P^Y and P^X reduced in size by half. An easy choice is to make:

$$P^Z = \frac{1}{2} \left(\frac{C^Y - C^X}{P^X} \right)$$

or any choice (with less noise symbols for instance) giving the same zonotope, geometrically.

Now we have found a potential P^Z , we rewrite inequalities 6 and 7:

$$\|(C^Z - C^X)t\|_1 \leq \frac{1}{2} (\|(C^Y - C^X)t\|_1 + \|P^Y t\|_1 - \|P^X t\|_1) \quad (8)$$

$$\|(C^Z - C^Y)t\|_1 \leq \frac{1}{2} (\|(C^Y - C^X)t\|_1 + \|P^X t\|_1 - \|P^Y t\|_1) \quad (9)$$

In case $\gamma_{lin}(P^X) = \gamma_{lin}(P^Y)$, inequalities 8 and 9 can be made into equalities, choosing C^Z to have entries being the mean of the corresponding entries of C^X and C^Y , exactly realizing $\|(C^Z - C^X)t\|_1 = \frac{1}{2}\|(C^Y - C^X)t\|_1 = \|(C^Z - C^Y)t\|_1$. In that case, we can choose for example

$$P^Z = \left(\frac{\frac{1}{2}(C^Y - C^X)}{P^X} \right).$$

□

We do not fully discuss here the general case, but some intuition is given in Example 3. A good over-approximation of a mub is given by the above formula applied to $X' = (C^X, P^U)$ and $Y' = (C^Y, P^U)$, where P^U is such that $\gamma(P^X) \cup \gamma(P^Y) \subseteq \gamma(P^U)$.

Example 2. Consider now:

$$X = \begin{pmatrix} 1 + 2\varepsilon_1 \\ -1 + \varepsilon_1 - 2\varepsilon_2 \end{pmatrix} Y = \begin{pmatrix} 3 + \varepsilon_1 \\ 1 + 2\varepsilon_1 - \varepsilon_2 \end{pmatrix}$$

Using Lemma 9, we find

$$Z = \begin{pmatrix} 2 + 1.5\varepsilon_1 + \eta_1 - 0.5\eta_2 \\ 1.5\varepsilon_1 - 1.5\varepsilon_2 + \eta_1 + 0.5\eta_2 + 0.5\eta_3 \end{pmatrix}$$

which is a mub indeed. It is depicted in Figure 4.

Convergence acceleration The trouble with Lemma 9 is that it may produce a lot of new noise symbols, thus being not always easily applicable. We thus introduce a less refined join operator, which also very often allows to accelerate fixpoint convergence. For any interval i , we note $mid(i)$ its center. Let $\alpha \wedge \beta$ denote the minimum of the two real numbers, and $\alpha \vee \beta$ their maximum. We define

$$\operatorname{argmin}_{|\cdot|}(\alpha, \beta) = \{\gamma \in [\alpha \wedge \beta, \alpha \vee \beta], |\gamma| \text{ minimal}\}$$

Lemma 10. *Let $X = (C^X, P^X)$ and $Y = (C^Y, P^Y)$ be two perturbed affine sets in $\mathcal{M}(n+1, p) \times \mathcal{M}(m, p)$. We define $Z = (C^Z, P^Z) = X \nabla Y \in \mathcal{M}(n+1, p) \times \mathcal{M}(m+p, p)$ by:*

- $c_{0,k}^Z = mid(\gamma(\pi_k(X)) \cup \gamma(\pi_k(Y)))$ for all $k = 1, \dots, p$
- $c_{i,k}^Z = \operatorname{argmin}_{|\cdot|}(c_{i,k}^X, c_{i,k}^Y)$ for all $i = 1, \dots, n, k = 1, \dots, p$
- $p_{j,k}^Z = \operatorname{argmin}_{|\cdot|}(p_{j,k}^X, p_{j,k}^Y)$ for all $j = 1, \dots, m, k = 1, \dots, p$
- $p_{m+j,j}^Z = \sup \gamma(\pi_j(X)) \cup \gamma(\pi_j(Y)) - \sup \gamma(c_{0,j}^Z + \sum_{i=1}^n c_{i,j}^Z \varepsilon_j + \sum_{i=1}^m p_{i,j}^Z \eta_j)$ for all $j = 1, \dots, p$
- $p_{m+j,k}^Z = 0$ for all $j, k = 1, \dots, p$ with $j \neq k$

Then Z is an upper bound of X and Y such that for all $k = 1, \dots, p$, $\gamma(\pi_k(Z)) = \gamma(\pi_k(X)) \cup \gamma(\pi_k(Y))$

PROOF. We prove that $X \leq Z$, the property that $\gamma(\pi_k(Z)) = \gamma(\pi_k(X)) \cup \gamma(\pi_k(Y))$ being easy to check (by construction!). Now, we want to prove negativity, for all $t \in \mathbb{R}^p$ of:

$$\sum_{i=0}^n \left| \sum_{k=1}^p (c_{i,k}^Z - c_{i,k}^X) t_k \right| + \sum_{j=1}^m \left| \sum_{k=1}^p p_{j,k}^X t_k \right| - \sum_{j=1}^m \left| \sum_{k=1}^p p_{j,k}^Z t_k \right| - \sum_{j=1}^p \left| p_{m+j,j}^Z t_j \right|$$

By the triangular inequality, the sum of the first 2 terms is less or equal to

$$\sum_{i=0}^n \left| \sum_{k=1}^p (c_{i,k}^Z - c_{i,k}^X) t_k \right| + \sum_{j=1}^m \left| \sum_{k=1}^p (p_{j,k}^Z - p_{j,k}^X) t_k \right|$$

then using it again for each sum, is less or equal to

$$\sum_{k=1}^p |t_k| \left(\sum_{i=1}^n |c_{i,k}^Z - c_{i,k}^X| + \sum_{j=1}^m |p_{j,k}^Z - p_{j,k}^X| \right)$$

But we know by [13], section 3.5.1, where this operator for acceleration of convergence was defined, that for all $k = 1, \dots, p$, $\sum_{i=0}^n |c_{i,k}^Z - c_{i,k}^X| + \sum_{j=1}^m |p_{j,k}^Z - p_{j,k}^X| \leq |p_{m+k,k}^Z|$. So overall, this is less than $\sum_{k=1}^p |p_{m+k,k}^Z t_k|$. \square

This ∇ operation may be sub-optimal, but the concretisations on each axis (i.e. the immediate concretisation of all program variables) are optimal. Also, while its cost of computation is still of $O((n + m)p)$, it may produce far less perturbation symbols, and may even kill over some of the central symbols.

Example 3. Consider X and Y as defined in Example 2:

$$Z' = X \nabla Y = \begin{pmatrix} 1.5 + \varepsilon_1 + 1.5\eta_1 \\ \varepsilon_1 - \varepsilon_2 + 2\eta_2 \end{pmatrix}$$

Note that (see Figure 4) Z' has the smallest possible concretisations on the x and y coordinates: respectively $[-1, 4]$ and $[-4, 4]$, which is strictly better than what we had with the mub Z in Example 2 (respectively $[-1, 5]$ and $[-5, 5]$). But it does not share perturbation noise symbols, as Z does, and along direction $t = {}^t(-1, 1)$, we find $Z't = y - x \in [-6, 3]$ which is not as good as we had with Z : $Zt \in [-5, 1]$. In fact, Z and Z' are not comparable under \leq . But Z' is not a mub, just consider:

$$Z'' = \begin{pmatrix} 1.5 + \varepsilon_1 + 0.5\eta_1 + \eta_2 \\ \varepsilon_1 - \varepsilon_2 + \eta_1 + \eta_3 \end{pmatrix}$$

We can prove that $Z'' \leq Z'$, and in fact, Z'' is a mub. Z'' has the smallest possible concretisations on the x and y axes as shown in Figure 4, but $Z''t \in [-5, 2]$ which is not as accurate as Zt : Z and Z'' are also incomparable.

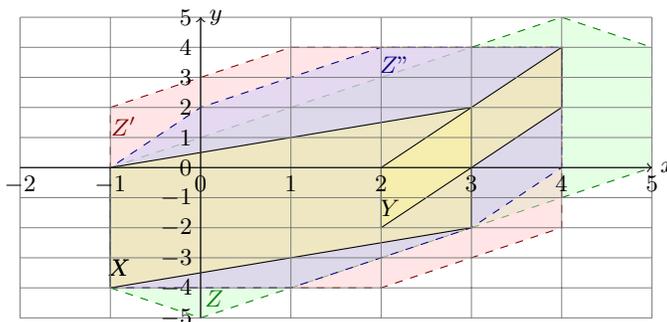

Fig. 4. Z and Z'' are mubs for X and Y , while Z' is not

4.6 Kleene-like iteration schemes

We first note that we have enough mubs so that to hope for a Kleene-like iteration:

Lemma 11. *Let S be a bounded and countable directed set of perturbed affine sets all in $\mathcal{M}(n+1, p) \times \mathcal{M}(m, p)$. Then there exists a minimal upper bound for S , given by the limit matrices $\lim_{u \rightarrow \infty} X_u = (\lim_{u \rightarrow \infty} C^u, \lim_{u \rightarrow \infty} P^u)$.*

PROOF. We thus have X a perturbed affine set and

$$S = \{X_0, \dots, X_u, \dots\}$$

with $X_i \leq X_j \leq x$ for all i, j with $i \leq j$. Thus for all $t \in \mathbb{R}^p$,

$$\|(C^j - C^i)t\|_1 \leq \|P^j t\|_1 - \|P^i t\|_1$$

This entails first that $(\|P^u t\|_1)_{u \in \mathbf{N}}$ is increasing. Also, as for all u , $X_u \leq X$, this means that $0 \leq \|(C^X - C^u)t\|_1 \leq \|P^X t\|_1 - \|P^u t\|_1$, so the sequence $(\|P^u t\|_1)_{u \in \mathbf{N}}$ is also bounded by $\|P^X t\|_1$. Hence it is converging for all t .

This means also that $\|(C^j - C^i)t\|_1$ can be made as small as wanted with i and j sufficiently big, for all t . Hence, as $(\mathbb{R}^p, \|\cdot\|_1)$ is a Banach space, this means that for all t , $C^u t$ converges when u goes to the infinity. This entails the convergence of the sequence of matrices C^u in the *fixed dimension* space $\mathcal{M}(n+1, p)$, similarly for P^u in $\mathcal{M}(m, p)$.

Note that this finite dimension requirement is necessary. As for polyhedra, an infinite union of zonotopes might not be a zonotope: just think of a zonotope with a growing number of faces, approximating a circle.

The fact that the limit matrices define a minimal upper bound is an obvious consequence of the fact that the order \leq is closed in $(\mathcal{M}(n+1, p) \times \mathcal{M}(m, p))^2$, and of basic properties of limits. \square

As we have only this form of bounded completeness, and not unconditional completeness, our iteration schemes will be parameterized by a large interval I : as soon as the current iterate leaves I^p , we end iteration by \top .

The following formalizes the iteration scheme and stopping criterion used, parametrized by a join operator (for instance, the ∇ operator defined in Lemma 10):

Definition 9. *Given an upper-bound operator U , the U -iteration scheme for a strict, continuous and increasing functional F on perturbed affine sets (extended with a formal \perp and \top), is as follows:*

- Start with $X_0 = \perp$
- Then iterate: $X_{u+1} = X_u U F(X_u)$ starting with $u = 1$
 - if $\gamma(X_{u+1}) \subseteq \gamma(X_u)$ then stop with X_{u+1}
 - if $\gamma(X_{u+1}) \not\subseteq I^p$, then end with \top

Note that our semantic operators only produce continuous and increasing functionals F . Also, initial and cyclic unfoldings are generally applied on top of this iteration scheme, so as to improve the precision of the analysis, see [8,13], and we cut the iteration after a finite time. We prove below the correctness of this scheme and of its stopping criterion. We also indicate its worst-case complexity:

Lemma 12. *Let F be a strict, continuous and increasing functional on perturbed affine sets. Consider the U -iteration scheme of Definition 9. Then $\gamma(X_{u+1}) \subseteq \gamma(X_u)$ can be checked in $O(p(n+m)^2)$ time, and guarantees that X_{u+1} is a post-fixed point of F .*

PROOF. We consider the countable and directed set $S = \{X_u \mid u \in \mathbf{N}\}$ where $X_u = U_{j=0}^u F^j(\perp)$. If it is unbounded, the U -iteration scheme will end up with \top in a finite time. Otherwise, apply Lemma 11. Define $G = FUId$; it is continuous and $G(\lim_{u \rightarrow \infty} X_u) = \lim_{u \rightarrow \infty} G(X_u) = \lim_{u \rightarrow \infty} X_u$, so the limit of the U -iteration scheme is a fixed-point of G , i.e. a post-fixed point of F . The test $\gamma(X_{u+1}) \subseteq \gamma(X_u)$, given that $X_u \leq X_{u+1}$ of course, is enough for checking if we reached the limit. We have already proven that if the stopping criterion is correct, then the U -iteration scheme converges towards \top or towards a post-fixed point of F , in practise in finite time, since we always cut the iteration scheme after a fixed number of iterations.

Suppose we apply our stopping criterion, i.e. $\gamma(X_{u+1}) \subseteq \gamma(X_u)$. But we have also $X_u \leq X_{u+1}$. Then for all $t \in \mathbb{R}^p$,

$$\begin{aligned} \|C^{X_{u+1}}t\|_1 - \|C^{X_u}t\|_1 &\leq \|P^{X_{u+1}}t\|_1 - \|P^{X_u}t\|_1 \\ \|(C^{X_{u+1}} - C^{X_u})t\|_1 &\leq \|P^{X_{u+1}}t\|_1 - \|P^{X_u}t\|_1 \end{aligned}$$

Adding these two inequalities together, we find:

$$\|C^{X_{u+1}}t\|_1 + \|(C^{X_{u+1}} - C^{X_u})t\|_1 \leq \|C^{X_u}t\|_1$$

But the triangular inequality also shows the inverse inequality, therefore:

$$\|C^{X_{u+1}}t\|_1 + \|(C^{X_{u+1}} - C^{X_u})t\|_1 = \|C^{X_u}t\|_1$$

So we have also:

$$\|(C^{X_{u+1}} - C^{X_u})t\|_1 \geq \|P^{X_u}t\|_1 - \|P^{X_{u+1}}t\|_1$$

This implies that for all $t \in \mathbb{R}^p$, $\|(C^{X_{u+1}} - C^{X_u})t\|_1 = 0$ and $\|P^{X_u}t\|_1 = \|P^{X_{u+1}}t\|_1$, i.e. $X_{u+1} \sim X_u$. Hence this implies that if we stop using this criterion, then we stop at a postfixed point of F . \square

In practice, we use the simpler $O((n+m)p)$ time test: $\forall k = 1, \dots, p, \|X_{u+1}t_k\|_1 \leq \|X_u t_k\|_1$ first, where t_k is the vector with all 0 entries, except at position k . It is only when this test is true that we compute the full test $\gamma(X_{u+1}) \subseteq \gamma(X_u)$.

Results on fixed-point computations, and comparisons with other abstract domains such as polyhedra, are described for preliminary versions of this domain in [8,13]. We plan to develop them for this domain in a longer version.

5 Conclusion and future work

We set up a formal framework for a fast and accurate abstract analysis based on zonotopes. There are several directions from there. First of all, we did not thoroughly detail the best way to compute (minimal) upper bounds, this will be done in the longer version.

Secondly, as can be noticed with the analysis of function \mathbf{f} of Section 2, the perturbation symbol η_1 can be associated with the `if` statement, with discrete values $\{-1, 1\}$ expressing whether the control flow went through the true or the false branch. This can be generalized to encode some of the interesting (semantical) disjunctive information, necessary for reaching precise invariants.

Third, a drawback of our domain is that tests are in general not interpreted. We are currently thinking of a simple and elegant extension, that would allow for computing accurate intersections.

Last but not least, we plan to carry on the study initiated in [13]. Given a program implementing a concrete numerical scheme, our abstraction gives us a perturbed numerical scheme, that can be studied for convergence similarly to the concrete scheme. We started with linear recursive filters where we had very good results, but this is likely to extend to some non-linear iterative schemes of wide interest.
