# Homogeneity and Homogenizability: Hard Problems for the Logic SNP 

Jakub Rydval $\square$ (ㄷ)<br>Technische Universität Wien, Vienna, Austria

#### Abstract

The infinite-domain CSP dichotomy conjecture extends the finite-domain CSP dichotomy theorem to reducts of finitely bounded homogeneous structures. Every finitely bounded homogeneous structure is uniquely described by a universal first-order sentence, and every reduct of such a structure by a sentence of the logic SNP. By Fraïssé's Theorem, testing the existence of a finitely bounded homogeneous structure for a given universal first-order sentence is equivalent to testing the amalgamation property for the class of its finite models. The present paper motivates a complexity-theoretic view on the classification problem for finitely bounded homogeneous structures. We show that this metaproblem is EXPSPACE-hard or PSPACE-hard, depending on whether the input is specified by a universal sentence or a set of forbidden substructures. By relaxing the input to SNP sentences and the question to the existence of a structure with a finitely bounded homogeneous expansion, we obtain a different meta-problem, closely related to the question of homogenizability. We show that this second meta-problem is already undecidable, even if the input SNP sentence comes from the Datalog fragment and uses at most binary relation symbols. As a byproduct of our proof, we also get the undecidability of some other properties for Datalog programs, e.g., whether they can be rewritten in the logic MMSNP, whether they solve some finite-domain CSP, or whether they define a structure with a homogeneous Ramsey expansion in a finite relational signature.

## 1 Introduction

Strict NP (SNP) is an expressive fragment of existential second-order logic and thus, by Fagin's Theorem, of the complexity class NP. If one only considers structures over a finite relational signature, then SNP can be obtained from the universal fragment of first-order logic simply by allowing existential quantification over relation symbols at the beginning of the quantifier prefix. In particular, universal first-order formulas themselves are SNP formulas. Despite the name, SNP already has the full power of NP [31]. In addition, this logic class has many connections to Constraint Satisfaction Problems (CSPs), which we use as the primary source of motivation for the present article. The CSP of a relational structure $\mathfrak{B}$, denoted by $\operatorname{CSP}(\mathfrak{B})$, is (the membership problem for) the class of all finite structures which homomorphically map to $\mathfrak{B}$. Every computational decision problem is polynomial-time equivalent to a CSP [13]. Many practically relevant problems like Boolean satisfiability or graph colorability can even be formulated as a finite-domain CSP, i.e., where the template $\mathfrak{B}$ can be chosen finite. The basic link from SNP to CSP is that every sentence of the monotone fragment of this logic defines a finite disjoint union of CSPs of (possibly
infinite) relational structures [9]. There are, however, some more nuanced connections, such as the one that led to the formulation of the Feder-Vardi conjecture, now known as the finitedomain CSP dichotomy theorem [51]. In their seminal work [31], Feder and Vardi showed that the Monotone Monadic fragment of SNP (MMSNP) exhibits a dichotomy between P and NP-completeness if and only if the seemingly less complicated class of all finite-domain CSPs exhibits such a dichotomy, ${ }^{1}$ they also conjectured the latter to be true. The logic class MMSNP contains all finite-domain CSPs, and many other interesting combinatorial problems, e.g., the problem of deciding whether the vertices of a given graph can be 2coloured without obtaining any monochromatic triangle [41]. The Feder-Vardi conjecture was confirmed in 2017 independently by Bulatov and Zhuk [24, 50].

There is a yet unconfirmed generalization of the Feder-Vardi conjecture, to CSPs of reducts of finitely bounded homogeneous structures, formulated by Bodirsky and Pinsker in 2011 [20]. Here we refer to it as the Bodirsky-Pinsker conjecture. A structure with a finite relational signature is finitely bounded if the class of all finite structures embeddable into it is definable by a universal first-order sentence, and homogeneous if every isomorphism between two of its finite substructures extends to an automorphism. Reducts of such structures are obtained simply by removing some of the original relations. A prototypical example of a structure that satisfies both finite boundedness and homogeneity is $(\mathbb{Q} ;<)$, the set of rational numbers equipped with the usual countable dense linear order without endpoints. It is a folklore fact that the class of reducts of finitely bounded homogeneous structures is closed under taking expansions of structures by first-order definable relations [9]. Roughly said, the condition imposed on the structures within the scope of the Bodirsky-Pinsker conjecture ensures that the CSP is in NP and that its template enjoys some of the universal-algebraic properties that have played an essential role in the proofs of the Feder-Vardi conjecture [7]. At the same time, it covers CSP-reformulations of many natural problems in qualitative reasoning, as well as all problems definable in MMSNP.

Every finitely bounded homogeneous structure is uniquely described by a universal firstorder sentence, and every reduct of such a structure by a sentence of the logic SNP. The CSPs of both kinds of structures are always definable in the monotone fragment of SNP. By Fraïssé's theorem, asking whether a given universal first-order sentence describes a finitely bounded homogeneous structure is equivalent to asking whether the class of its finite models has the Amalgamation Property (AP). This question has been considered many times in the context of the Lachlan-Cherlin classification programme for homogeneous structures [ $4,35,26$ ], and is known to be decidable in the case of binary signatures [37, 16]. It also appears as an open problem in Bodirsky's book on infinite-domain constraint satisfaction [9]. Whether a given SNP sentence describes a reduct of a finitely bounded homogeneous structure is a different question, closely related to homogenizability [2, 5, 29, 33]. To the best of our knowledge, neither of the two questions is known to be decidable in general. Hence, it is unclear which CSPs actually fall within the scope of the Bodirsky-Pinsker conjecture. Besides CSPs, these questions are also relevant to other areas of theoretical computer science such as verification of database-driven systems [22] or description logics with concrete domains $[38,6]$.

The Bodirsky-Pinsker conjecture. In 2016, Bodirsky and Mottet presented an elegant tool for lifting tractability from finite-domain constraint satisfaction to the infinite [19],

[^0]hereby establishing the first general link between the Feder-Vardi and the Bodirsky-Pinsker conjecture. Since then, their method has been used numerous times to prove new or reprove old complexity classification results for infinite-domain CSPs. One prominent such example is the universal-algebraic proof of the complexity dichotomy for MMSNP [17]. Conveniently enough, every MMSNP sentence defines a finite union of CSPs of structures within the scope of the Bodirky-Pinsker conjecture, so the two meta-questions from the previous paragraph were not relevant in this context. There is a prospect that the methods from [19] will also prove useful in proving a dichotomy for the even more general logic class Guarded Monotone SNP (GMSNP) introduced in [8]. Also GMSNP enjoys the above mentioned property of MMSNP [16], and hence avoids the two meta-questions.

However, outside of GMSNP there exists a regime where the methods from [19] definitely fall short, and where the two meta-questions become relevant. Consider for instance the dichotomy for temporal CSPs, i.e., for CSPs of structures with domain $\mathbb{Q}$ and whose relations are definable by a Boolean combination of formulas of the form $(x=y)$ or $(x<y)$, obtained by Bodirsky and Kára in 2010 [15]. At the present time, these problems are already very well understood; tractable temporal CSPs can always be solved by an algorithm that repeatedly searches for a set of potential minimal elements among the input variables, where each instance of the search is performed using an oracle for a tractable finite-domain CSP. The latter is generally determined by the shape of the Boolean combinations. E.g., in the case of $\operatorname{CSP}\left(\mathbb{Q} ;\left\{(x, y, z) \in \mathbb{Q}^{3} \mid(x=y<z) \vee(y=z<x) \vee(z=x<y)\right\}\right)$, solving the finite-domain CSP in question amounts to solving linear equations modulo 2 [15, 21]. It is known that the tractability results from [15] cannot be obtained using the reduction from [19].

In 2022, Mottet and Pinsker introduced the machinery of smooth approximations [43], which vastly generalizes the methods in [19]. The last section of their paper is devoted to temporal CSPs, and the authors manage to reprove a significant part of the dichotomy on just a few pages. They achieve this by applying some of their general results to first-order expansions of $(\mathbb{Q} ;<)$ and obtaining either NP-hardness for the CSP, or one of the two types of symmetry that played a fundamental role in the original proof from [15]. This symmetry can then be used to prove correctness of the reduction to a finite-domain CSP described above, but only under an explicit usage of the homogeneity of $(\mathbb{Q} ;<$ ) (see Proposition 3.1 in [21] and the last section of [43]). In contrast to the methods in [19] which only use homogeneity as a blackbox, this approach can be described as language-dependent.

A similar situation occurs in the case of phylogeny CSPs [14], which capture decision problems concerning the existence of a binary tree satisfying certain constraints imposed on its leaves. Tractable phylogeny CSPs are strikingly similar to tractable temporal CSPs; they can always be solved by an algorithm that repeatedly searches for a subdivision of the input variables into two parts, representing the two different branches below the root of a binary tree, where each instance of this search is performed using an oracle for a tractable finite-domain CSP. However, for tractable phylogeny CSPs, already the homogeneity of the infinite-domain CSP template is both sufficient and necessary for proving the correctness of the reduction to the finite-domain CSP (Theorem 6.13 and Lemma 6.12 in [14]). We can therefore speak of a case of extreme language-dependency. Temporal and phylogeny CSPs are special cases of CSPs of structures obtainable from the universal homogeneous binary tree [11] by specifying relations using first-order formulas. Achieving a complexity dichotomy in this context will require a non-trivial combination of the methods from [15] and [14].

An optimal way of approaching the conjecture would be to gain a very good understanding of the class of reducts of finitely bounded homogeneous structures, e.g., through some
sort of a classification. However, it is unclear how realistic this prospect is as model-theoretic properties often tend to be undecidable [25]. We remark that homogeneity is a vital part of the Bodirsky-Pinsker conjecture; this assumption can be weakened or strengthened but not dropped entirely, as otherwise we get a class that provably does not have a dichotomy [31, 9].

Contributions. In the present paper, we confirm the intractability of the two meta-questions. More specifically, we show that the first question is PSPACE-hard (Theorem 6) or EXPSPACEhard (Theorem 5), depending on the encoding of the input, and that the second question is undecidable (Theorem 11). Theorems 6 and 5 are proved in Section 3.1 by taking a proof-theoretic perspective on the AP for classes defined by universal Horn sentences. We show that, for some of these classes, the failures of the AP are in a $1: 1$ correspondence with the rejecting runs of certain Datalog programs verifying instances of the rectangle tiling problem. Here, by Datalog we mean the monotone Horn fragment of SNP. Theorem 11 is proved in Section 4, by analyzing model-theoretic properties of a very natural encoding of context-free grammars into Datalog sentences. As a byproduct of the proof, we also get the undecidability of some other properties for Datalog programs, e.g., whether they can be rewritten in the logic MMSNP, whether they solve some finite-domain CSP, or whether they define a structure with a homogeneous Ramsey expansion in a finite relational signature.

Our results highlight the need for a fundamentally new language-independent approach to the Bodirsky-Pinsker conjecture. The first steps in this direction were taken in the recent works of Mottet and Pinsker [43] and Bodirsky and Bodor [10]. Yet, the issues mentioned in the previous paragraphs are, as of now, unaddressed. To keep our results as general as possible, we formulate them for some reasonable promise relaxations of the two questions, i.e., where a subclass and a superclass of the positive instances are being separated from each other with the promise that the input never belongs to the complement of the subclass within the superclass. Omitted proofs or their parts can be found in the appendix.

## 2 Preliminaries

Relational structures. The set $\{1, \ldots, n\}$ is denoted by $[n]$, and we use the bar notation $\bar{t}$ for tuples. A (relational) signature $\tau$ is a set of relation symbols, each $R \in \tau$ with an associated natural number called arity. We say that $\tau$ is binary if it consists of symbols of arity $\leq 2$. A (relational) $\tau$-structure $\mathfrak{A}$ consists of a set $A$ (the domain) together with the relations $R^{\mathfrak{A}} \subseteq A^{k}$ for each $R \in \tau$ with arity $k$. An expansion of $\mathfrak{A}$ is a $\sigma$-structure $\mathfrak{B}$ with $A=B$ such that $\tau \subseteq \sigma, R^{\mathfrak{B}}=R^{\mathfrak{A}}$ for each relation symbol $R \in \tau$. Conversely, we call $\mathfrak{A}$ a reduct of $\mathfrak{B}$. The union of two $\tau$-structures $\mathfrak{A}$ and $\mathfrak{B}$ is the $\tau$-structure $\mathfrak{A} \cup \mathfrak{B}$ with domain $A \cup B$ and relations of the form $R^{\mathfrak{A} \cup \mathfrak{B}}:=R^{\mathfrak{A}} \cup R^{\mathfrak{B}}$ for every $R \in \tau$.

A homomorphism $h: \mathfrak{A} \rightarrow \mathfrak{B}$ for $\tau$-structures $\mathfrak{A}, \mathfrak{B}$ is a mapping $h: A \rightarrow B$ that preserves each relation of $\mathfrak{A}$, i.e., if $\bar{t} \in R^{\mathfrak{A}}$ for some $k$-ary relation symbol $R \in \tau$, then $h(\bar{t}) \in$ $R^{\mathfrak{B}}$. We write $\mathfrak{A} \rightarrow \mathfrak{B}$ if $\mathfrak{A}$ maps homomorphically to $\mathfrak{B}$. The Constraint Satisfaction Problem (CSP) of $\mathfrak{A}$, denoted by $\operatorname{CSP}(\mathfrak{A})$, is defined as the class of all finite structures which homomorphically map to $\mathfrak{A}$. An embedding is a homomorphism $h: \mathfrak{A} \rightarrow \mathfrak{B}$ that additionally satisfies the following condition: for every $k$-ary relation symbol $R \in \tau$ and $\bar{t} \in A^{k}$ we have $h(\bar{t}) \in R^{\mathfrak{B}}$ only if $\bar{t} \in R^{\mathfrak{A}}$. We write $\mathfrak{A} \hookrightarrow \mathfrak{B}$ if $\mathfrak{A}$ embeds to $\mathfrak{B}$. The age of $\mathfrak{A}$, denoted by age $(\mathfrak{A})$, is the class of all finite structures which embed to $\mathfrak{A}$. A substructure of $\mathfrak{A}$ is a structure $\mathfrak{B}$ over $B \subseteq A$ such that the inclusion map $i: B \rightarrow A$ is an embedding. An isomorphism is a surjective embedding. Two structures $\mathfrak{A}$ and $\mathfrak{B}$ are isomorphic if there exists an isomorphism from $\mathfrak{A}$ to $\mathfrak{B}$. An automorphism is an isomorphism from $\mathfrak{A}$ to $\mathfrak{A}$. The
orbit of a tuple $\bar{t} \in A^{k}$ in $\mathfrak{A}$ is the set $\{g(\bar{t}) \mid g$ is an automorphism of $\mathfrak{A}\}$. A structure $\mathfrak{A}$ is $\omega$-categorical if, for every $k \geq 1$, there are only finitely many orbits of $k$-tuples in $\mathfrak{A}$.

First-order logic. We assume that the reader is familiar with classical first-order logic as well as with basic preservation properties of first-order formulas, e.g., that every firstorder formula $\phi$ is preserved by isomorphisms; by embeddings if $\phi$ is existential, and by homomorphisms if $\phi$ is existential positive. For a first-order sentence $\Phi$, we denote the class of all its finite models by $\operatorname{fm}(\Phi)$. We say that a first-order formula is $k$-ary if it has $k$ free variables. For a first-order formula $\phi$, we use the notation $\phi(\bar{x})$ to indicate that the free variables of $\phi$ are among $\bar{x}$. This does not mean that the truth value of $\phi$ depends on each entry in $\bar{x}$. We assume that equality $=$ as well as the nullary predicate symbol $\perp$ for falsity are always available when building first-order formulas. Thus, atomic $\tau$-formulas, or $\tau$-atoms for short, over a relational signature $\tau$ are of the form $\perp,(x=y)$, and $R(\bar{x})$ for some $R \in \tau$. We say that a formula is equality-free if it does not contain any occurrence of the default equality predicate. If $\phi$ is a disjunction of possibly negated $\tau$-atoms, then we define the Gaifman graph of $\phi$ as the undirected graph whose vertex set consists of all free variables of $\phi$ and where two distinct variables $x, y$ form an edge if and only if they appear jointly in a negative atom of $\phi$. Let $\Phi$ be a universal $\tau$-sentence in prenex normal form whose quantifier-free part $\phi$ is in CNF. We call $\Phi$ Horn if every clause of $\phi$ is Horn, i.e., contains at most one positive disjunct. We call $\Phi$ complete if the Gaifman graph of each clause of $\phi$ is complete. It is a folklore fact that, if $\Phi$ is complete, then $\operatorname{fm}(\Phi)$ is preserved by unions.

SNP and its fragments. An $S N P \tau$-sentence is a second-order sentence $\Phi$ of the form $\exists X_{1}, \ldots, X_{n} \forall \bar{x}$. $\phi$ where $\phi$ is a quantifier-free formula in CNF over $\tau \cup\left\{X_{1}, \ldots, X_{n}\right\}$. We call $\Phi$ monadic if $X_{i}$ is unary for every $i \in[n]$; monotone if $\phi$ does not contain any positive $\tau$-atoms (in particular no positive equality atoms); and guarded if, for every positive atom $\beta$ there exists a negative atom $\alpha$ containing all variables of $\beta$. Note that all notions from the previous paragraph easily transfer to SNP sentences viewed as universal sentences in an extended signature. The monadic monotone and the guarded monotone fragments of SNP are denoted by MMSNP and GMSNP, respectively. The monotone Horn fragment of SNP is commonly known as the logic programming language Datalog. When we say that a Datalog program $\Phi$ solves the CSP of a structure $\mathfrak{B}$, we simply mean that $\operatorname{fm}(\Phi)=\operatorname{CSP}(\mathfrak{B})$.

Homogeneity, homogenizability, and finite boundedness. A countable structure $\mathfrak{S}$ is homogeneous if every isomorphism between two finite substructures of $\mathfrak{S}$ extends to an automorphism of $\mathfrak{S}$. Clearly, every homogeneous structure in a finite relational signature is $\omega$-categorical. Homogeneous structures arise as limit objects of well-behaved classes of finite structures in the sense of Theorem 1. Let $\mathcal{K}$ be a class of finite structures in a finite relational signature $\tau$ closed under isomorphisms and substructures. We say that $\mathcal{K}$ has the amalgamation property $(\mathrm{AP})$ if, for all $\mathfrak{B}_{1}, \mathfrak{B}_{2} \in \mathcal{K}$ there exists $\mathfrak{C} \in \mathcal{K}$ with $f_{1}: \mathfrak{B}_{1} \hookrightarrow \mathfrak{C}$ and $f_{2}: \mathfrak{B}_{2} \hookrightarrow \mathfrak{C}$ such that $\left.f_{1}\right|_{B_{1} \cap B_{2}}=\left.f_{2}\right|_{B_{1} \cap B_{2}}$. We refer to $\mathfrak{C}$ as an amalgam of $\mathfrak{B}_{1}$ and $\mathfrak{B}_{2}$. Note that, for a class closed under isomorphisms and substructures, the AP is implied by the property of being closed under unions (also called free amalgams).

- Theorem 1 (Fraïssé). For a class $\mathcal{K}$ of finite structures in a finite relational signature $\tau$, the following are equivalent:
- $\mathcal{K}$ is the age of an up to isomorphism unique countable homogeneous $\tau$-structure;
- $\mathcal{K}$ is closed under isomorphisms, substructures, and has the AP.

As already mentioned in the introduction, the structure $(\mathbb{Q} ;<)$ is homogeneous because every local isomorphism can be extended to an automorphism using a piecewise affine transformation. Its age is the class of all finite strict linear orders.

A countable structure $\mathfrak{S}$ is homogenizable if it is a reduct of a homogeneous structure $\mathfrak{H}$ over a finite relational signature such that $\mathfrak{S}$ and $\mathfrak{H}$ have the same sets of automorphisms [29]. Whenever this happens, by the theorem of Ryll-Nardzewski, all relations of $\mathfrak{H}$ are firstorder definable in $\mathfrak{S}$ [32]. One might say that $\mathfrak{S}$ already has all the relations necessary for homogeneity but they perhaps do not all have names. A prototypical example of this phenomenon is the universal "homogeneous" binary tree, which is homogenizable but not homogeneous, see, e.g., Proposition 3.2 in [11]. We call a class $\mathcal{K}$ of finite structures in a finite relational signature $\tau$ homogenizable if it forms the age of a homogenizable structure.

For a class $\mathcal{N}$ of finite structures in a finite relational signature $\tau$, the class $\operatorname{Forb}_{e}(\mathcal{N})$ consists of all finite $\tau$-structures which do not embed any member of $\mathcal{N}$. Following the terminology in [39], we say that a class $\mathcal{K}$ of finite structures in a finite relational signature is finitely bounded if there exists a finite $\mathcal{N}$ such that $\mathcal{K}=\operatorname{Forb}_{e}(\mathcal{N})$. We refer to $\mathcal{N}$ as a set of bounds for $\mathcal{K}$, and define the size of $\mathcal{N}$ as the sum of the cardinalities of the domain and the relations of all structures in $\mathcal{N}$. A structure $\mathfrak{S}$ is finitely bounded if its age is finitely bounded. We say that a class $\mathcal{K}$ is finitely bounded homogenizable if it forms the age of a reduct $\mathfrak{R}$ of a finitely bounded homogeneous structure $\mathfrak{H}$ such that $\mathfrak{R}$ and $\mathfrak{H}$ have the same sets of automorphisms. Sufficient conditions for finitely bounded homogenizability were provided by Hubička and Nešetřil [34], generalizing previous work of Cherlin, Shelah, and Shi [27].

## 3 The first meta-problem

By Theorem 1, every homogeneous structure is uniquely described by its age. Consequently, every finitely bounded homogeneous structure is uniquely described by a finite set of bounds. It is known that the question whether $\operatorname{Forb}_{e}(\mathcal{N})$ has the AP for a given finite set of bounds $\mathcal{N}$ can be tested algorithmically in the case where the signature is binary [37]. This decidability result is based on the following observation. A one-point amalgamation diagram is an input $\mathfrak{B}_{1}, \mathfrak{B}_{2}$ to the AP where $\left|B_{1} \backslash B_{2}\right|=\left|B_{2} \backslash B_{1}\right|=1$.

- Proposition 2 ([37]). A class of finite relational $\tau$-structures that is closed under isomorphisms and substructures has the AP if and only if it has the AP restricted to one-point amalgamation diagrams.

As a consequence of Proposition 2, if $\tau$ is binary and $\operatorname{Forb}_{e}(\mathcal{N})$ does not have the AP, then the size of a smallest counterexample to the AP is polynomial in the size of $\mathcal{N}$ [16]. Such a counterexample can be non-deterministically guessed and verified using a coNP-oracle, which places the problem at the second level of the polynomial hierarchy (Theorem 15 in [6]).

There is a second, arguably more practical, equivalent definition of finite boundedness. Namely, a class $\mathcal{K}$ of finite structures in a finite relational signature is finitely bounded if and only if there exists a universal sentence $\Phi$ such that $\mathcal{K}=\mathrm{fm}(\Phi)$. Using this definition, it is easy to see that $(\mathbb{Q} ;<)$ is finitely bounded because its age, the class of all finite strict linear orders, admits a finite universal axiomatization (irreflexivity, transitivity, and totality). From a complexity-theoretical perspective, the two definitions are equivalent only up to a single-exponential blow-up in one direction. Given a finite set of bounds $\mathcal{N}$, we can obtain a universal sentence $\Phi$ of size polynomial in the size of $\mathcal{N}$ satisfying $\operatorname{fm}(\Phi)=\operatorname{Forb}_{e}(\mathcal{N})$ by describing each structure in $\mathcal{N}$ up to isomorphism using a quantifier-free formula. However,
given a universal sentence $\Phi$, it can be the case that a smallest $\mathcal{N}$ satisfying $\mathrm{fm}(\Phi)=$ $\operatorname{Forb}_{e}(\mathcal{N})$ is of size single-exponential in the size of $\Phi$. The reason is that obtaining $\mathcal{N}$ from $\Phi$ is comparable to rewriting $\Phi$ in DNF. Consequently, the algorithm from [16] only gives us a relatively weak upper bound for the case where the inputs are specified by universal sentences.

- Proposition 3. Let $\Phi$ be a universal sentence over a finite binary relational signature $\tau$. If $\mathrm{fm}(\Phi)$ does not have the $A P$, then the size of a smallest counterexample to the $A P$ is at most single-exponential in the size of $\Phi$. Consequently, the question whether $\operatorname{fm}(\Phi)$ has the AP is decidable in coNEXPTIME.

The upper bound provided by Proposition 3 is not unreasonable since a smallest counterexample to the AP might be of size exponential in the size of the input sentence even if the signature is binary. Very little progress has been done on signatures containing symbols of arities larger than 2. In particular, it is not even known whether the AP is decidable for finitely bounded classes in general. The scenario where this is not the case is not unrealistic since the closely related joint embedding property is undecidable already for finitely bounded classes of graphs [23]. If the AP turns out to be undecidable as well (for finitely bounded classes), then the Bodirsky-Pinsker conjecture addresses a class of structures with an undecidable membership problem. However, it seems that, at least to some extent, the decidability issue can be ignored by only using homogeneity as a blackbox. This was demonstrated in the recent work [44] on the complexity of CSPs of homogeneous uniform hypergraphs, whose classification remains an open problem [4]. We remark that the question is already open in the following case, where we can only prove PSPACE-hardness.

- Theorem 4. Given a universal Horn sentence $\Phi$ over a finite relational signature that is binary except for one ternary symbol, the question whether $\operatorname{fm}(\Phi)$ has the AP is PSPACEhard.

The next theorem states that testing the AP becomes properly harder than in the binary case if we do not impose any restrictions on the input (unless the exponential hierarchy collapses). The fact that Theorem 5 also holds for the strong version of the AP might be of independent interest to model-theorists. The strong version of the AP is when $\mathfrak{C} \in \mathcal{K}$ and $f_{i}: \mathfrak{B}_{i} \hookrightarrow \mathfrak{C}$ for $i \in\{1,2\}$ can always be chosen so that $f_{1}\left(B_{1}\right) \cap f_{2}\left(B_{2}\right)=f_{1}\left(B_{1} \cap B_{2}\right)$.

- Theorem 5. Given a universal sentence $\Phi$ over a finite signature, the question whether $\mathrm{fm}(\Phi)$ has the strong AP or not even the AP is EXPSPACE-hard, even when the number of variables in $\Phi$ is bounded by a constant.

The next theorem is a variant of Theorem 5 in the setting where the input is specified by a set of bounds instead of a universal sentence. This setting can be compared to the situation where, in Theorem 5 , the quantifier-free part of $\Phi$ is required to be in DNF. As a consequence, we cannot profit from succintness of general universal sentences, which leads to a weaker PSPACE lower bound on the complexity.

- Theorem 6. Given a finite set $\mathcal{N}$ of finite structures over a finite signature, the question whether $\operatorname{Forb}_{e}(\mathcal{N})$ has the strong AP or not even the AP is PSPACE-hard, even when the domain size for the structures in $\mathcal{N}$ is bounded by a constant.

### 3.1 Proofs of Theorem 5 and Theorem 6

Our proofs of Theorem 5 and Theorem 6 are based on the fact that, if $\Phi$ is a universal Horn sentence such that $\operatorname{fm}(\Phi)$ does not have the AP, then every counterexample to the AP has
the form of a particular Horn clause which can be derived from $\Phi$ in a syntactical manner. By padding each Horn clause in $\Phi$ with auxiliary negative atoms and hereby increasing its "degree of completeness," we gain some control over the form of the counterexamples to the AP. When this is performed in a careful and systematic way, the counterexamples to the AP can be brought into a 1:1 correspondence with the rejecting runs of certain Datalog programs. In our case, such programs verify the validity of tilings w.r.t. given input parameters to a bounded tiling problem. This is the main technical contribution of the present article.

Let $\Phi$ be an equality-free universal Horn sentence over a relational signature $\tau$, and let $\phi(\bar{x}), \psi(\bar{x}, \bar{y})$ be equality-free conjunctions of atomic $\tau$-formulas. We write $\psi(\bar{x}, \bar{y}) \leq_{\Phi} \phi(\bar{x})$ if, for every atomic $\tau$-formula $\chi(\bar{x})$ other than equality, $\Phi \models \forall \bar{x}, \bar{y}(\psi(\bar{x}, \bar{y}) \Rightarrow \chi(\bar{x}))$ implies $\Phi \models \forall \bar{x}(\phi(\bar{x}) \Rightarrow \chi(\bar{x}))$.

- Lemma 7. Let $\Phi$ be an equality-free universal Horn sentence over a relational signature $\tau$. Then the following are equivalent:

1. $\mathrm{fm}(\Phi)$ has the strong $A P$.
2. $\mathrm{fm}(\Phi)$ has the $A P$.
3. If $\phi(\bar{x}), \phi_{1}\left(\bar{x}, y_{1}\right)$, and $\phi_{2}\left(\bar{x}, y_{2}\right)$ are equality-free conjunctions of atomic formulas, where $y_{1}$ and $y_{2}$ are distinct variables not contained in $\bar{x}$, such that, for both $i \in\{1,2\}$, every atom in $\phi_{i}\left(\bar{x}, y_{i}\right)$ contains the variable $y_{i}$ and $\phi(\bar{x}) \wedge \phi_{i}\left(\bar{x}, y_{i}\right) \leq_{\Phi} \phi(\bar{x})$, then $\phi(\bar{x}) \wedge$ $\phi_{1}\left(\bar{x}, y_{1}\right) \wedge \phi_{2}\left(\bar{x}, y_{2}\right) \leq_{\Phi} \phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right)$.
Let $\Phi$ be an equality-free universal Horn sentence and $\psi$ a Horn clause over a relational signature $\tau$. An $S L D$-derivation of $\psi$ from $\Phi$ is a finite sequence of Horn clauses $\psi_{0}, \ldots, \psi_{s}=$ $\psi$ such that $\psi_{0}$ is a conjunct in $\Phi$ and, for every $i \in[s]$, there exists a Horn clause $\phi_{i}$ which is, up to renaming of variables, a conjunct in $\Phi$, and such that $\psi_{i}$ is obtained from $\psi_{i-1}$ by replacing a negative atom of $\psi_{i-1}$ that appears positively in $\phi_{i}$ with all negative atoms of $\phi_{i}$. We say that $\psi_{i}$ is a resolvent of $\psi_{i-1}$ and $\phi_{i}$. We call $\psi$ a weakening of a clause $\psi^{\prime}$ if $\psi^{\prime}$ can be obtained from $\psi$ by removing any amount of atoms. In particular, $\psi$ is a weakening of itself. There exists an $S L D$-deduction of $\psi$ from $\Phi$, written as $\Phi \vdash \psi$, if $\psi$ is a tautology or a weakening of a Horn clause $\psi^{\prime}$ that has an SLD-derivation from $\Phi$. The following theorem presents a fundamental property of equality-free universal Horn sentences.

- Theorem 8 (Theorem 7.10 in [45]). Let $\Phi$ be an equality-free universal Horn sentence and $\psi$ an equality-free Horn clause, both in a fixed signature $\tau$. Then $\Phi \models \psi$ if and only if $\Phi \vdash \psi$.

The hardness proofs are by polynomial-time reductions from the complements of two well-known bounded versions of the tiling problem. Consider the signature $\tau$ consisting of the two binary symbols $P_{h}, P_{v}$, as well as the four unary symbols $P_{\ell}, P_{r}, P_{t}, P_{b}$. For natural numbers $m, n \geq 1$, the $\tau$-structure $\Re_{m, n}$ has the domain $[m] \times[n]$ and relations

$$
\begin{aligned}
P_{\ell}^{\Re_{m, n}} & :=[m] \times\{1\}, P_{r}^{\Re_{m, n}}:=[m] \times\{n\}, P_{b}^{\Re_{m, n}}:=\{1\} \times[n], P_{t}^{\Re_{m, n}}:=\{m\} \times[n], \\
P_{h}^{\Re_{m, n}} & :=\{((i, j),(i+1, j)) \mid i \in[n-1], j \in[m]\}, \\
P_{v}^{\Re_{m, n}}: & :=\{((i, j),(i, j+1)) \mid i \in[n], j \in[m-1]\} .
\end{aligned}
$$

The rectangle tiling problem asks whether, given a natural number $n$ and a finite $\tau$-structure $\mathfrak{T}$, there exists a natural number $m$ such that $\mathfrak{R}_{m, n} \rightarrow \mathfrak{T}$. In contrast to the better-known NP-complete square tiling problem, one dimension of the tiling grid is not part of the input and is existentially quantified instead. As a result, the problem becomes PSPACEcomplete $[28,49] .{ }^{2}$ One can further increase the complexity by allowing a succinct encoding

[^1]of the space bound. The input remains the same but now we ask for a a rectangle tiling with $2^{n}$ columns. Analogously to the natural complete problems based on Turing machines, this yields a decision problem that is complete for the complexity class EXPSPACE [47].

Theorem 5 is proved by polynomial-time reduction from the complement of the exponential rectangle tiling problem. From every input, we construct a universal sentence $\Phi$ of polynomial size such that $\operatorname{fm}(\Phi)$ has the AP if and only if there exists no exponential rectangle tiling satisfying the given parameters. The sentence $\Phi$ is almost Horn but, sometimes, disjunctions and equality atoms are used in premises of implications to represent exponentially many Horn clauses in a universal sentence of polynomial size. In the text that follows, we allow ourselves to still call such sentences Horn. Our encoding is very compact; each row, i.e., an ordered sequence of $2^{n}$-many tiles, is represented using a constant amount of variables. This is achieved by storing the information about each individual row in binary using $(n+1)$-ary atoms whose entries always contain at most three variables. We refer to the variables representing rows of the tiling as path nodes. In order to check the tiling from bottom to top, i.e., parse a chain of path nodes, we require each pair of subsequent path nodes to be verified by a set of $2^{n}$-many verifier nodes. This process ensures the vertical consistency of the tiling as well as the presence of $2^{n}$-many tiles in every row. The precise number of verifier nodes is achieved using combinations of $n$ pairs of unary atoms.

To control the occurrence of amalgamation failures, we first introduce a binary symbol $E$ and two unary symbols $L, R$. Atoms with these symbols serve no other purpose than to ensure that almost each conjunct in $\Phi$ is complete, i.e., defines a class of structures that is preserved by taking unions and hence has the AP. More concretely, the premise of almost every Horn clause in $\Phi$ has a subformula of the form $L\left(y_{1}\right) \wedge R\left(y_{2}\right) \wedge \bigwedge_{i \in[k]} E\left(y_{1}, x_{i}\right) \wedge$ $E\left(y_{2}, x_{i}\right) \wedge \bigwedge_{j \in[k]} E\left(x_{i}, x_{j}\right)$ making the Horn clause almost complete, with the exception of one potentially missing edge in the Gaifman graph between $y_{1}$ and $y_{2}$. Our intention is to make this missing edge the only place at which potential faulty one-point amalgamation diagrams can be built (see Figure 1). The sentence $\Phi$ is defined as $\Phi_{1} \wedge \Phi_{2}$, where the two parts are described below.

The first part $\Phi_{1}$ does not yet explain how our reduction works, but ensures that it does not fall apart, e.g., due to ill-behaved identifications of variables. For every $\alpha \in T$, the signature $\tau$ contains an $(n+1)$-ary symbol $T_{\alpha}$. The first $n$ arguments in a $T_{\alpha}$-atom serve as binary counters, and the last argument carries a given path node $p$. Suppose that the variables 0 and 1 represent the bits 0 and 1 , respectively. Then each atomic formula $T_{\alpha}\left(c_{1}, \ldots, c_{n}, p\right)$ with $c_{1}, \ldots, c_{n} \in\{0,1\}$ represents the situation in which a tile $\alpha$ is present in the $p$-th row and in the $\left(1+\sum_{k \in[n]}\left(c_{k}=1\right) \cdot 2^{n-k}\right)$-th column. First, we want to ensure the horizontal consistency of the tiling. To this end, for every pair $(\alpha, \beta) \in T^{2} \backslash P_{h}^{\mathfrak{T}}$, we include in $\Phi_{1}$ a complete Horn sentence without positive atoms ensuring that two horizontally adjacent positions in the $p$-th row cannot be tiled with $\alpha$ and $\beta$. Here, we encode the successor relation w.r.t. binary addition using a combination of equalities: $\left(c_{n+1}, \ldots, c_{2 n}\right)$ is the successor of $\left(c_{1}, \ldots, c_{n}\right)$ if and only if there exists $j \in[n]$ such that $c_{i}=c_{i+n} \in\{0,1\}$ for every $i \in[j-1]$, $c_{j}=0$ and $c_{n+j}=1$, and $c_{i}=1$ and $c_{i+n}=0$ for every $i \in[n] \backslash[j]$. This encoding only makes sense if 0 and 1 truly represent the bits 0 and 1 , so we introduce a simple mechanism (in terms of a Horn sentence) for distinguishing between the variables 0 and 1. Next, we want to ensure that every position in the $p$-th row is occupied by at most one tile. To this end, for every $(\alpha, \beta) \in T^{2}$ with $\alpha \neq \beta$, we include

$$
\forall p, \mathrm{O}, 1, c_{1}, \ldots, c_{n}\left(T_{\alpha}\left(c_{1}, \ldots, c_{n}, p\right) \wedge T_{\beta}\left(c_{1}, \ldots, c_{n}, p\right) \wedge \bigwedge_{i \in[n]}\left(c_{i}=\mathrm{O} \vee c_{i}=\mathbf{1}\right) \Rightarrow \perp\right)
$$

as a conjunct in $\Phi_{1}$. Finally, we want to ensure that each verifier node $v$ represents at most
one number from $\left[2^{n}\right]$. For every $i \in[n], \tau$ contains two unary symbols $\mathrm{O}_{i}$ and $1_{i}$ which will be used to encode numbers in binary. We include $\forall v\left(\bigvee_{i \in[n]} \mathrm{O}_{i}(v) \wedge 1_{i}(v) \Rightarrow \perp\right)$ as the last conjunct in $\Phi_{1}$. Now the idea is that the combinations of atomic formulas $0_{i}(v)$ and $1_{i}(v)$ at a verifier node $v$ will be compared with the combinations of 0 and 1 in atomic formulas $T_{\alpha}\left(c_{1}, \ldots, c_{n}, p\right)$. The Horn sentences in the second part of $\Phi$ will be formulated so that verifying the presence of all $2^{n}$ atoms of the form $T_{\alpha}\left(c_{1}, \ldots, c_{n}, p_{1}\right)$ at a path node $p_{1}$ using verifier nodes $v_{1}, \ldots, v_{2^{n}}$ is the only possible way to progress to a next path node $p_{2}$. As a consequence, we do not need to add an explicit requirement for rows, represented by path nodes, to be completely tiled from left to right. For the same reason, we also do not need to add an explicit requirement for verifier nodes to represent at least one number from [ $2^{n}$ ].

We now proceed with the sentence $\Phi_{2}$, which explains how the parsing of a tiling actually works. The parsing of a tiling starts from a path node $p$ representing a row whose leftmost position contains a tile that can be present in the bottom left corner of a tiling grid. This must be confirmed by a verifier node, in which case a 6 -ary $Q_{b}$-atom is derived, representing the fact that the leftmost column of the $p$-th row has been checked. To this end, we include in $\Phi_{2}$ suitable Horn sentences for every $\alpha \in P_{\ell}^{\mathfrak{T}} \cap P_{b}^{\mathfrak{T}}$. These sentences form the non-complete part of $\Phi$; we intentionally leave a missing edge between $y_{1}$ and $y_{2}$ in the Gaifman graph to enable the formation of potential AP-counterexamples. Using $2^{n}$-many verifier nodes and propagation of $Q_{b}$-atoms, the whole bottom row is checked for the presence of tiles. Their horizontal consistency already follows from the conditions imposed on path nodes by $\Phi_{2}$ and needs not to be checked during this step. To this end, we include in $\Phi_{2}$ suitable Horn sentences for every $\alpha \in P_{b}^{\mathcal{T}}$. After the $p$-th row has been checked by a $2^{n}$-th verifier node, we mark $p$ with a $Q$-atom indicating that the parsing can progress to a successor path node. To this end, we include in $\Phi_{2}$ suitable Horn sentences for every $\alpha \in P_{b}^{\mathfrak{T}} \cap P_{r}^{\mathfrak{T}}$. The successor relation for path nodes is represented by the binary symbol $S$, and the certificate of vertical verification for pairs $\left(p_{1}, p_{2}\right)$ of successive path nodes is represented by the 7 -ary symbol $Q_{v}$. For every $(\alpha, \beta) \in P_{v}^{\mathfrak{T}} \cap\left(P_{\ell}^{\mathfrak{T}}\right)^{2}$, we include in $\Phi_{2}$ a Horn sentence verifying the vertical consistency of the leftmost positions in the rows $p_{1}$ and $p_{2}$ and deriving the first $Q_{v}$-atom containing $p_{1}$ and $p_{2}$, but only if there is a $Q$-atom containing $p_{1}$. Next, for every $(\alpha, \beta) \in P_{v}^{\mathfrak{T}}$, we include in $\Phi_{2}$ a Horn sentence verifying the vertical consistency for the intermediate positions by deriving further $Q_{v}$-atoms containing $p_{1}$ and $p_{2}$. And finally, for every $(\alpha, \beta) \in P_{v}^{\mathfrak{T}} \cap\left(P_{r}^{\mathfrak{T}}\right)^{2}$, we include in $\Phi_{2}$ a Horn sentence verifying the vertical consistency of the leftmost positions in the rows $p_{1}$ and $p_{2}$ and deriving the first $Q$-atom containing $p_{2}$ only. The top row is verified using a 6 -ary symbol $Q_{t}$ similarly as the bottom row; however, the verification of the rightmost position in the top row results in the derivation of $\perp$.

Proof of Theorem 5. We first argue that $\Phi$ is equivalent to a particular Horn sentence, to which we can apply Lemma 7. By construction, the quantifier-free part of each conjunct in $\Phi$ has the form of an implication where the premise possibly also contains instances of disjunction, which are not allowed in Horn clauses, but no instances of negation. Therefore, it can be rewritten as a conjunction of Horn clauses by converting the premise into positive DNF and then considering each disjunct as a separate premise. As a result, the size of the sentence increases exponentially, but this does not matter for the purpose of the proof. Subsequently, all equality atoms can be eliminated by replacing each variable $c_{i}$ with either o or 1 . We denote the resulting Horn sentence by $\bar{\Phi}$ and the two parts stemming from $\Phi_{1}$ and $\Phi_{2}$ by $\bar{\Phi}_{1}$ and $\bar{\Phi}_{2}$, respectively.
" $\Rightarrow$ " Suppose that there exists a tiling $f: \mathfrak{R}_{m, 2^{n}} \rightarrow \mathfrak{T}$. Guided by $f$, we define a onepoint amalgamation diagram $\mathfrak{B}_{1}, \mathfrak{B}_{2} \in \operatorname{fm}(\bar{\Phi})$ which has no amalgam in $\operatorname{fm}(\bar{\Phi})$ (see Figure 1). The domains are $B_{i}:=\left\{y_{i}, p_{1}, \ldots, p_{m}, v_{1}, \ldots, v_{2^{n}}, \mathbf{o}, 1\right\}$ for $i \in\{1,2\}$, and the relations are

Figure 1 An illustration of an AP-counterexample representing a valid tiling of an exponential rectangle with $m$ rows and $2^{n}$ columns.
given by the following conjunctions of atomic formulas. We require $T_{\alpha}\left(c_{1}, \ldots, c_{n}, p_{j}\right)$ for $c_{1}, \ldots, c_{n} \in\{0,1\}$ if and only if $f\left(1+\sum_{k \in[n]}\left(c_{k}=1\right) \cdot 2^{n-k}, j\right)=i$. Next, we require all of the $L, R$, and $E$-atoms necessary for enabling the Horn clauses in $\mathfrak{B}_{1} \cup \mathfrak{B}_{2}$. Finally, we require $\bigwedge_{i \in[m-1]} S\left(p_{i}, p_{i+1}\right)$ to define a successor chain through path nodes, and $\mathrm{O}_{i}\left(v_{j}\right)$ or $1_{i}\left(v_{j}\right)$ if and only if $j=1+\sum_{k \in[n]} \lambda_{k} \cdot 2^{n-k}$ for $\lambda_{1}, \ldots, \lambda_{n} \in\{0,1\}$ and $\lambda_{i}=0$ or $\lambda_{i}=1$, respectively. Clearly, the tiling atoms are placed correctly and the verifier nodes correctly represent values in $\left[2^{n}\right]$. Since $R^{\mathfrak{B}_{1}}=\emptyset$ and $L^{\mathfrak{B}_{2}}=\emptyset$, we have $\mathfrak{B}_{1}, \mathfrak{B}_{2} \models \bar{\Phi}_{2}$. Since $f$ is horizontally consistent, we have $\mathfrak{B}_{1}, \mathfrak{B}_{2} \models \bar{\Phi}_{1}$, i.e., $\mathfrak{B}_{1}, \mathfrak{B}_{2} \in \operatorname{fm}(\bar{\Phi})$. But since $f$ is also vertically consistent and $\bar{\Phi}_{2}$ is a universal Horn sentence, we have $\mathfrak{C} \not \equiv \bar{\Phi}_{2}$ for every $\tau$-structure $\mathfrak{C}$ with a homomorphism from $\mathfrak{B}_{1} \cup \mathfrak{B}_{2}$. Hence, $\mathrm{fm}(\bar{\Phi})$ does not have the AP.
$" \Leftarrow$ " Suppose that $\operatorname{fm}(\bar{\Phi})$ does not have the AP. Then there exists a counterexample to item (3) in Lemma 7, i.e., there exists a Horn clause $\psi$ of the form $\phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right) \wedge$ $\phi_{2}\left(\bar{x}, y_{2}\right) \Rightarrow \chi$, where $\phi, \phi_{1}$, and $\phi_{2}$ satisfy the prerequisites of item (3) in Lemma 7 and $\chi\left(\bar{x}, y_{1}\right)$ is an atomic $\tau$-formula other than equality, such that

$$
\begin{align*}
& \bar{\Phi} \models \forall \bar{x}, y_{1}, y_{2}\left(\phi \wedge \phi_{1} \wedge \phi_{2} \Rightarrow \chi\right)  \tag{1}\\
& \bar{\Phi} \not \equiv \forall \bar{x}, y_{1}\left(\phi \wedge \phi_{1} \Rightarrow \chi\right) \tag{2}
\end{align*}
$$

We choose $\psi$ minimal with respect to the number of its atomic subformulas. By Theorem 8 , $\psi$ has an SLD-deduction from $\bar{\Phi}$. Note that, by $(2), \chi\left(\bar{x}, y_{1}\right)$ cannot be a subformula of $\phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right)$. Also, $\chi\left(\bar{x}, y_{1}\right)$ cannot be a subformula of $\phi_{2}\left(\bar{x}, y_{2}\right)$ because every atom in $\phi_{2}\left(\bar{x}, y_{2}\right)$ contains the variable $y_{2}$ which does not appear in $\chi\left(\bar{x}, y_{1}\right)$. Hence, $\chi\left(\bar{x}, y_{1}\right)$ is not a subformula of $\phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right) \wedge \phi_{2}\left(\bar{x}, y_{2}\right)$, i.e., $\psi$ is not a tautology. Consequently, $\psi$ is a weakening of a Horn clause $\psi^{\prime}$ which has an SLD-derivation $\psi_{0}^{\prime}, \ldots, \psi_{s}^{\prime}=\psi^{\prime}$ from $\bar{\Phi}$. Recall that every atom from $\psi^{\prime}$ appears in $\psi$.
$\triangleright$ Claim 9. $\quad \bar{\Phi}_{2} \vdash \psi^{\prime}$.
Proof. We start by showing that $\psi_{0}^{\prime}$ is a conjunct of $\bar{\Phi}_{2}$. Suppose, on the contrary, that $\psi_{0}^{\prime}$ is a conjunct of $\bar{\Phi}_{1}$. Then $\psi^{\prime}$ does not contain any positive atom because, by construction, Horn sentences in $\bar{\Phi}_{1}$ do not contain any positive atoms. By construction, in $\bar{\Phi}$ there is no Horn clause containing a positive atom that occurs negatively in a Horn clause from $\bar{\Phi}_{1}$, i.e., it is impossible to take resolvents of $\psi_{0}^{\prime}$ and Horn clauses from $\bar{\Phi}$. It follows that $s=0$. Also, every Horn clause from $\bar{\Phi}_{1}$ is complete. Since there is no edge between $y_{1}$ and $y_{2}$ in the

Gaifman graph of $\psi$, and, for $i \in\{1,2\}$, each atom in $\phi_{i}$ contains the variable $y_{i}$, either $\phi_{1}$ or $\phi_{2}$ must be empty. Since $\psi^{\prime}$ does not contain any positive atom and $\phi(\bar{x}) \wedge \phi_{i}\left(\bar{x}, y_{i}\right) \leq \bar{\Phi} \phi(\bar{x})$ for both $i \in\{1,2\}$, we get a contradiction to (2). Thus, $\psi_{0}^{\prime}$ must be a conjunct of $\bar{\Phi}_{2}$. Since no Horn clause in $\bar{\Phi}_{1}$ contains a positive atom, no Horn clause from $\bar{\Phi}_{1}$ can be used as a resolvent. We conclude that $\psi^{\prime}$ has an SLD-derivation from $\bar{\Phi}_{2}$.
$\triangleright$ Claim 10. $\psi^{\prime}$ contains no positive atoms, and no atoms with a symbol from $\left\{Q_{b}, Q_{v}, Q_{t}, Q\right\}$.
Proof. By the construction of $\bar{\Phi}_{2}$, for every $i \in[s]$, if $\psi_{i-1}^{\prime}$ contains variables $z_{1}, z_{2}$ such that
every atomic subformula with a symbol from $\left\{Q_{b}, Q_{v}, Q_{t}, Q\right\}$
contains $z_{1}$ in its 1st and $z_{2}$ in its 2 nd argument, respectively,
then this is also the case for $\psi_{i}^{\prime}$, for the same variables $z_{1}, z_{2}$ up to renaming. Since every possible choice of $\psi_{0}^{\prime}$ from $\bar{\Phi}_{2}$ initially satisfies (3), it follows via induction that (3) holds for $\psi^{\prime}=\psi_{s}^{\prime}$ for some variables $z_{1}, z_{2}$. Next, we show that $\left\{z_{1}, z_{2}\right\}=\left\{y_{1}, y_{2}\right\}$ holds for the pair $z_{1}, z_{2}$ satisfying (3) for $\psi^{\prime}$. Suppose, on the contrary, that both $z_{1}$ and $z_{2}$ are among $\bar{x}, y_{1}$ or $\bar{x}, y_{2}$. By construction, the only Horn clauses in $\bar{\Phi}_{2}$ that are not complete have the property that the incompleteness is only due to one missing edge in the Gaifman graph between two distinguished variables satisfying (3). Therefore, for every $i \in[s], \psi_{i}^{\prime}$ is a resolvent of $\psi_{i-1}^{\prime}$ and a Horn clause from $\bar{\Phi}_{2}$ which is almost complete except possibly for one missing edge in the Gaifman graph between a pair of variables which must be substituted for the pair $\left(z_{1}, z_{2}\right)$ satisfying (3) for $\psi_{i-1}^{\prime}$. Since the variables $y_{1}$ and $y_{2}$ do not appear together in any atom in $\psi^{\prime}$ and $\left\{z_{1}, z_{2}\right\} \neq\left\{y_{1}, y_{2}\right\}$, they also do not appear together in any atom during the SLD-derivation. Then it follows from the fact that $\phi, \phi_{1}$, and $\phi_{2}$ satisfy the prerequisites of item (3) in Lemma 7 that we already have $\bar{\Phi}_{2} \vdash \forall \bar{x}, y_{1}\left(\phi \wedge \phi_{1} \Rightarrow \chi\right)$, a contradiction to (2). Since $\left\{z_{1}, z_{2}\right\}=\left\{y_{1}, y_{2}\right\}$ holds for the pair $z_{1}, z_{2}$ satisfying (3) for $\psi^{\prime}, \psi^{\prime}$ cannot contain any negative atoms with a symbol from $\left\{Q_{b}, Q_{v}, Q_{t}, Q\right\}$. Suppose that the conclusion of $\psi_{0}^{\prime}$ is not $\perp$. Then, by construction, $\psi^{\prime}$ contains a positive atom with a symbol from $\left\{Q_{b}, Q_{v}, Q_{t}, Q\right\}$. But then, since $z_{1}, z_{2}$ with $\left\{z_{1}, z_{2}\right\}=\left\{y_{1}, y_{2}\right\}$ satisfy (3) for $\psi^{\prime}$, the said positive atom in $\psi^{\prime}$ contains both variables $y_{1}$ and $y_{2}$. This leads to a contradiction to (1) where we assume that the positive atom in $\psi$ may may only contain variables from $\bar{x}, y_{1}$. Thus the conclusion of $\psi_{0}^{\prime}$ is $\perp$, which means that $\chi$ equals $\perp$ due to the minimality assumption.

It remains to show that the existence of such $\psi^{\prime}$ implies the existence of a tiling $f: \mathfrak{R}_{m, 2^{n}} \rightarrow$ $\mathfrak{T}$. By the first and the second claim, the conclusion of $\psi_{0}^{\prime}$ is $\perp$. Since $\psi^{\prime}$ does not contain any atoms with a symbol from $\left\{Q_{b}, Q_{v}, Q_{t}, Q\right\}$, the last such atom must have been eliminated from $\psi_{s-1}^{\prime}$ by taking a resolvent with one of the incomplete Horn clauses in $\bar{\Phi}_{2}$. By the construction of $\bar{\Phi}_{2}$, to obtain $\psi^{\prime}$ through an SLD-derivation $\psi_{0}^{\prime}, \ldots, \psi_{s}^{\prime}=\psi^{\prime}$ from $\bar{\Phi}_{2}$, all Horn clauses introduced in the definition of $\bar{\Phi}_{2}$ must have been used in the intended order. Recall that we have replaced each variable $c_{i}$ in $\Phi_{2}$ with either 0 or 1 while rewriting $\Phi_{2}$ as an Horn sentence. Every Horn clause from $\bar{\Phi}_{2}$ has the property that every positive atomic subformula has a symbol from $\left\{Q_{b}, Q_{v}, Q_{t}, Q\right\}$ and contains all variables that appear in a negative atomic subformula, with the following two exceptions. First, verifier nodes are not carried over in any atoms because their only contribution is the encoding of a unique number. Second, after a pair of successive rows has been checked by deriving a $Q_{v}$-atom containing a $2^{n}$-th verifier node, the variable representing the lower row is not carried over in any atom because it is no longer needed. Since $\phi, \phi_{1}$, and $\phi_{2}$ satisfy the prerequisites of item (3) in Lemma 7, no ill-behaved variable identifications might have occurred during the SLD-derivation above as otherwise, we would have $\bar{\Phi}_{1} \models \forall \bar{x}, y_{1}\left(\phi \wedge \phi_{1} \Rightarrow \chi\right)$, a
contradiction to (2). Consequently, the SLD-derivation must have the full intended length $\left(2^{n}+1\right) \cdot m$ for some $m \geq 1$, because every intermediate stage starts and ends with verifier nodes encoding the numbers $2^{n}$ and 1, respectively, and one can only progress in steps which decrement the encoded number by one. Clearly, the SLD-derivation witnesses the existence of $f: \mathfrak{R}_{m, 2^{n}} \rightarrow \mathfrak{T}$.

We continue with the proof of Thoeorem 6 . This time, we reduce from the complement of the basic rectangle tiling problem. As in the proof of Theorem 5, we first include in $\tau$ the two auxiliary unary symbols $L, R$ and the binary auxiliary symbol $E$. However, the encoding of the tiles is slightly different. We include in $\tau$ a symbol $I$ of arity $\left\lceil\log _{2}|T| \cdot n\right\rceil+1$. The first $\left\lceil\log _{2}|T| \cdot n\right\rceil$ entries serve as binary counters to represent the pairs $(i, \alpha) \in[n] \times T$ in binary, and the last entry carries a path node representing a row of the tiling grid. Each pair $(i, \alpha) \in[n] \times T$ is to be interpreted as the fact that the $i$-th column in the row represented by a particular path node contains the tile $\alpha$. The reason for this choice of encoding is that we aim to construct a universal sentence $\Phi$ which is equivalent to a set of forbidden substructures $\mathcal{N}$ of size polynomial in $|T| \cdot n$. To achieve this, we use a constant number of symbols whose arity is logarithmic in the size of the input.

Suppose that 0 and 1 are two variables representing the bits 0 and 1, respectively. For each pair $(i, \alpha) \in[n] \times T$, the ternary formula $\operatorname{TILE}_{i, \alpha}(\mathbf{0}, 1, p)$ is the $I$-atom whose last entry contains the variable $p$ and the first $\left\lceil\log _{2}|T| \cdot n\right\rceil$ entries contain the variables 0 and 1 in the unique way that represents the number $i \cdot \alpha$ in binary when read from left to right. Note that the number of such formulas is polynomial in the size of the input to the tiling problem. In contrast to the proof of Theorem 5, it is not necessary to introduce any verifier nodes as the number of columns in the tiling grid is polynomial in the size of the input. The sentence $\Phi$ is defined similarly as in the proof of Theorem 5 , so we only provide a general overview and highlight the main differences. We want each row to be horizontally consistent. For all $i \in[n-1]$ and $(\alpha, \beta) \in T^{2} \backslash P_{h}^{\mathfrak{T}}$, we include the following sentence as a conjunct in $\Phi_{1}$ :

$$
\forall p, \mathbf{o}, 1\left(\psi(\mathbf{o}, 1) \wedge \operatorname{TILE}_{i, \alpha}(\mathbf{o}, 1, p) \wedge \operatorname{TILE}_{i+1, \beta}(\mathbf{o}, 1, p) \Rightarrow \perp\right)
$$

where $\psi(\mathbf{O}, \mathbf{1})$ represents a simple mechanism for distinguishing between O and 1 . We also want each position in a given row to be occupied by at most one tile. For all $i \in[n], \alpha, \beta \in T$, we include the following sentence as a conjunct in $\Phi_{1}$ :

$$
\forall p, \mathbf{o}, 1\left(\operatorname{TILE}_{i, \alpha}(\mathbf{o}, 1, p) \wedge \operatorname{TILE}_{i, \beta}(\mathbf{0}, 1, p) \Rightarrow \perp\right)
$$

As in the proof of Theorem 6, we do not need to include an explicit condition stating that each row must be completely tiled from left to right. For the purpose of verifying the validity of a tiling, we include in $\tau$ a 5 -ary symbol $Q$, a $\left(\left\lceil\log _{2}|T| \cdot n\right\rceil+4\right)$-ary symbol $Q_{v}$, and two ( $\left\lceil\log _{2}|T| \cdot n\right\rceil+3$ )-ary symbols $Q_{b}, Q_{t}$. For each pair $(i, \alpha) \in[n] \times T$, the formulas

$$
\operatorname{BOT}_{i, \alpha}\left(\mathrm{o}, 1, p, y_{1}, y_{2}\right), \quad \operatorname{TOP}_{i, \alpha}\left(\mathrm{o}, 1, p, y_{1}, y_{2}\right), \quad \text { and } \quad \operatorname{VERT}_{i, \alpha}\left(\mathrm{o}, 1, p_{1}, p_{2}, y_{1}, y_{2}\right)
$$

are defined analogously to $\operatorname{TILE}_{i, \alpha}(\mathbf{0}, 1, p)$ but using the $Q_{b}, Q_{t}$ and $Q_{v}$-atoms instead. We use them to verify the bottom row, top row, and the vertical consistency of a given tiling. In contrast to $\mathrm{TILE}_{i, \alpha}$, the parameter $\alpha$ is not important in $\mathrm{BOT}_{i, \alpha}, \mathrm{TOP}_{i, \alpha}$, and VERT $_{i, \alpha}$.

We now explain how to convert $\Phi$ into a set of forbidden substructures. Let $\mathcal{N}$ be the class of all $\tau$-structures with the domain [i] for some $i \in[6]$ that do not satisfy $\Phi$. Since $\Phi$ only uses six variables, we have $\operatorname{fm}(\Phi)=\operatorname{Forb}_{e}(\mathcal{N})$. It remains to show that there exists a polynomial that bounds the size of $\mathcal{N}$. Since there is a constant number of domains of structures in $\mathcal{N}$ and their sizes are also constant, it is enough to show that there exists a
polynomial that bounds the number of structures in $\mathcal{N}$. The only non-constant parameters in the construction are the four symbols $I, Q_{b}, Q_{t}$, and $Q_{v}$ whose arity grows logarithmically with $|T| \cdot n$. Thus, there exists a constant $c$ such that the number of structures in $\mathcal{N}$ is bounded by $c \cdot\left(2^{\left[\log _{2}|T| \cdot n\right\rceil}\right)^{4} \leq c \cdot(2 \cdot|T| \cdot n)^{4}$. The rest is analogous to the proof of Theorem 5.

## 4 The second meta-problem

Every reduct $\mathfrak{R}$ of a finitely bounded homogeneous structure $\mathfrak{H}$ is uniquely described by an SNP sentence, which can be obtained from a universal sentence for age $(\mathfrak{H})$ by existentially quantifying all the surplus predicates upfront. This is (arguably) the most natural representation for such structures. The second meta-problem asks whether a given SNP $\tau$-sentence $\Phi$ is logically equivalent to an SNP $\tau$-sentence $\Psi=\exists Y_{1}, \ldots, Y_{m} \forall \bar{y} . \psi$ such that $\mathrm{fm}(\forall \bar{y} \cdot \psi)$ has the AP in the extended signature $\tau \cup\left\{Y_{1}, \ldots, Y_{m}\right\}$. We are additionally interested in the refinement of the question where we require the homogeneous structure from Theorem 1 associated to $\mathrm{fm}(\forall \bar{y} . \psi)$ to have the same set of automorphisms as its reduct to the original signature $\tau$. This amounts to asking whether $\mathrm{fm}(\Phi)$ is finitely bounded homogenizable.

MMSNP was presented in [31] as a large subclass of SNP which has a dichotomy between P and NP-completeness if and only if the class of all finite-domain CSPs has one. The latter has been confirmed, and the dichotomy for MMSNP has received a new universal-algebraic proof within the programme attacking the Bodirsky-Pinsker conjecture [18]. The new proof relies on the observation that every MMSNP sentence $\Phi$ is equivalent to a finite disjunction $\Phi_{1} \vee \cdots \vee \Phi_{n}$ of MMSNP sentences such that, for every $i \in[n]$, there exists a reduct $\Re_{i}$ of a finitely bounded homogeneous structure $\mathfrak{H}_{i}$ such that $\operatorname{fm}\left(\Phi_{i}\right)=\operatorname{CSP}\left(\mathfrak{R}_{i}\right) .^{3}$ Moreover, the structure $\mathfrak{H}$ can be chosen so that its age has the Ramsey property, which plays an essential role in an argument in [18] showing that the authors correctly identified all of the tractable cases. The exact definition of this property is not essential to the present article and is therefore omitted. GMSNP was first introduced in [40] in its seemingly weaker form $\mathrm{MMSNP}_{2}$, as a generalization of MMSNP where "monadic" second-order variables may also range over atomic formulas. It was later shown that relaxing the above requirement for monotone SNP to guardedness does not result in a more expressive logic [8]. There is a prospect that GMSNP will also have dichotomy between P and NP-completeness since it enjoys similar model-theoretic properties as MMSNP [16].

Theorem 11 is the most general version of our undecidability result. The second item might give the impression that one cannot effectively distinguish between CSPs of reducts of finitely bounded structures and CSPs of reducts of finitely bounded homogeneous structures. Recall that the former class does not have a dichotomy [31, 9]. However, as indicated by the formulation of the second item, all CSPs of reducts of finitely bounded homogeneous structures in the proof of Theorem 11 are in fact finite-domain CSPs, for which there is a dichotomy. Therefore, Theorem 11 merely shows that SNP sentences are an exceptionally bad choice of an input to the question, albeit one that is sometimes used (see, e.g., [5, 42]).

- Theorem 11. Given a Datalog sentence $\Phi$ over a finite binary signature, it is undecidable whether:

1. $\Phi$ is logically equivalent to a monadic Datalog sentence, or $\Phi$ is not even logically equivalent to any GMSNP sentence;

[^2]2. $\Phi$ simultaneously satisfies the following three conditions:
$=\mathrm{fm}(\Phi)$ is the CSP of a finite structure,
$=\mathrm{fm}(\Phi)$ is a finitely bounded homogenizable class,
$=\mathrm{fm}(\Phi)$ is the age of a reduct of a finitely bounded homogeneous Ramsey structure, or $\operatorname{fm}(\Phi)$ is not even the CSP or the age of any $\omega$-categorical structure.

### 4.1 A proof of Theorem 11

As usual, the Kleene plus and the Kleene star of a finite set of symbols $\Sigma$, denoted by $\Sigma^{+}$ and $\Sigma^{*}$, are the sets of all finite words over $\Sigma$ of lengths $\geq 1$ and $\geq 0$, respectively.

A context-free grammar (CFG) is a 4 -tuple $\mathscr{G}=(N, \Sigma, P, S)$ where $N$ is a finite set of non-terminal symbols, $\Sigma$ is a finite set of terminal symbols, $P$ is a finite set of production rules of the form $A \rightarrow w$ where $A \in N$ and $w \in(N \cup \Sigma)^{+}, S \in N$ is the start symbol. For $u, v \in(N \cup \Sigma)^{+}$we write $u \rightarrow_{G} v$ if there are $x, y \in(N \cup \Sigma)^{+}$and $(A \rightarrow w) \in P$ such that $u=x A y$ and $v=x w y$. The language of $\mathscr{G}$ is $L(\mathscr{G}):=\left\{w \in \Sigma^{+} \mid S \rightarrow_{\mathscr{G}}^{*} w\right\}$, where $\rightarrow_{\mathscr{G}}^{*}$ denotes the transitive closure of $\rightarrow \varphi$. Note that with this definition the empty word $\epsilon$ can never be an element of $L(\mathscr{G})$; some authors use a modified definition that also allows rules that derive $\epsilon$, but for our purposes the difference is not essential. A context-free grammar is called (left-)regular if its production rules are always of the form $A \rightarrow a$ or $A \rightarrow B a$ for non-terminal symbols $A, B$ and a terminal symbol $a$. For a finite set $\Sigma$, we call a set $L \subseteq \Sigma^{+}$ regular if it is the language of a regular grammar with terminal symbols $\Sigma$.

- Example 12. Consider the CFG $\mathscr{G}$ with a single terminal symbol $a$, non-terminal symbols $S, A, B, C$, and production rules $S \rightarrow a, S \rightarrow a a, S \rightarrow a a a, S \rightarrow A a, A \rightarrow B a, B \rightarrow C a$, $C \rightarrow C a$, and $C \rightarrow a$. Clearly, $\mathscr{G}$ is not regular. However, $L(\mathscr{G})=\{a\}^{+}$is regular.

Let $\mathscr{G}=(N, \Sigma, P, S)$ be a CFG. The signature $\tau_{\Sigma}$ consists of the unary symbols $I, T$ and the binary symbols $R_{a}$ for every $a \in \Sigma$, and the signature $\tau_{N}$ consists of a binary symbol $R_{a}$ for every element $a \in N$. For $a_{1} \ldots a_{n} \in \Sigma^{+}$, we set $\phi_{a_{1} \ldots a_{n}}\left(x_{1}, \ldots, x_{n+1}\right):=$ $\bigwedge_{i \in[n]} R_{a_{i}}\left(x_{i}, x_{i+1}\right)$. Let $\bar{\Phi}_{\mathscr{G}}$ be the universal Horn sentence over the signature $\tau_{\Sigma} \cup \tau_{N}$ whose quantifier-free part contains, for every $(A, w) \in P$, the Horn clause $\phi_{w}\left(x_{1}, \ldots, x_{|w|+1}\right) \Rightarrow$ $R_{A}\left(x_{1}, x_{|w|+1}\right)$, and additionally the Horn clause $I\left(x_{1}\right) \wedge R_{S}\left(x_{1}, x_{2}\right) \wedge T\left(x_{2}\right) \Rightarrow \perp$. Then $\Phi_{G}$ is the Datalog sentence obtained from $\bar{\Phi}_{\mathscr{G}}$ by existentially quantifying all symbols from $\tau_{N}$ upfront. This encoding of CFGs into Datalog programs is standard (Exercise 12.26 in [1]), and the correspondence provided by the next lemma can be shown via a straightforward induction. For a proof, we refer the reader to [46].

- Lemma 13. For a $\tau_{\Sigma}$-structure $\mathfrak{A}$, we have $\mathfrak{A} \models \Phi_{g}$ if and only if, for every $w \in L(\mathscr{G})$,

$$
\mathfrak{A} \models \forall x_{1}, \ldots, x_{|w|+1}\left(I\left(x_{1}\right) \wedge \phi_{w}\left(x_{1}, \ldots, x_{|w|+1}\right) \wedge T\left(x_{|w|+1}\right) \Rightarrow \perp\right) .
$$

The following lemma is proved by establishing a connection between the well-known Myhill-Nerode correspondence and $\omega$-categoricity, under the addition of several auxiliary results from [30, 16].

- Lemma 14. Let $\mathscr{G}$ be a context-free grammar. Then the following are equivalent:

1. $L(\mathscr{G})$ is regular.
2. $\Phi_{\mathscr{G}}$ is equivalent to monadic Datalog sentence.
3. $\Phi_{g}$ is equivalent to a GMSNP sentence.
4. $\mathrm{fm}\left(\Phi_{\mathscr{G}}\right)$ is the CSP of a finite structure.
5. $\mathrm{fm}\left(\Phi_{\mathscr{G}}\right)$ is the CSP of an $\omega$-categorical structure.
6. $\operatorname{fm}\left(\Phi_{\mathscr{G}}\right)$ is the age of a reduct of a finitely bounded homogeneous Ramsey structure.
7. $\mathrm{fm}\left(\Phi_{\mathcal{G}}\right)$ is the age of an $\omega$-categorical structure.
8. $\operatorname{fm}\left(\Phi_{\mathscr{G}}\right)$ is finitely bounded homogenizable.

Proof of Theorem 11. It is well-known that the questions whether $L(\mathscr{G})$ is regular for a given context-free grammar $\mathscr{G}$ is undecidable, see, e.g., Theorem 6.6.6 in [48]. Hence, all eight equivalent conditions in Lemma 14 are undecidable for $\mathscr{G}$.

## A Omitted proofs

For a tuple $\bar{t}$ indexed by a set $I$, the value of $\bar{t}$ at the position $i \in I$ is denoted by $\bar{t}[i]$.
The disjoint union of two $\tau$-structure $\mathfrak{A}$ and $\mathfrak{B}$ is obtained by taking the union of two copies of $\mathfrak{A}$ and $\mathfrak{B}$ with disjoint domains. We call $\Phi$ connected if the Gaifman graph of each clause of $\phi$ is complete connected. It is a folklore fact that, if $\Phi$ is connected, then $\mathrm{fm}(\Phi)$ is preserved by disjoint unions. Note that connectivity easily transfers to SNP sentences viewed as universal sentences in an extended signature.

## A. 1 Proof of Proposition 3

Proposition 3. Let $\Phi$ be a universal sentence over a finite binary relational signature $\tau$. If $\operatorname{fm}(\Phi)$ does not have the $A P$, then the size of a smallest counterexample to the AP is at most single-exponential in the size of $\Phi$. Consequently, the question whether $\operatorname{fm}(\Phi)$ has the $A P$ is decidable in coNEXPTIME.

Proof. Suppose that $\mathrm{fm}(\Phi)$ does not have the AP. By Proposition 2, we may assume that a counterexample to the AP for $\operatorname{fm}(\Phi)$ is a one-point amalgamation diagram formed by two structures $\mathfrak{B}_{1}, \mathfrak{B}_{2} \in \operatorname{fm}(\Phi)$. Let $k$ be the number of variables in $\Phi$. We define $\mathcal{N}$ as the set of all $\tau$-structures $\mathfrak{A}$ such that $\mathfrak{A}\left|\neq \Phi,|A| \leq k\right.$, and $A=[|A|]$. Clearly, $\operatorname{fm}(\Phi)=\operatorname{Forb}_{e}(\mathcal{N})$ and the size of $\mathcal{N}$ is at most single-exponential in the size of $\Phi$. Therefore, by the estimates on the size of a smallest counterexample from the proof of Theorem 4 in [16], we can assume that the size of $\mathfrak{B}_{1}$ and $\mathfrak{B}_{2}$ is at most single-exponential in the size of $\Phi$. First, we must verify that $\mathfrak{B}_{1}, \mathfrak{B}_{2} \in \operatorname{fm}(\Phi)$. This can be done in time exponential in the size of $\Phi$ simply by evaluating the quantifier-free part of $\Phi$ on all possible inputs. Subsequently, we must verify that no amalgam $\mathfrak{C} \in \operatorname{fm}(\Phi)$ of $\mathfrak{B}_{1}$ and $\mathfrak{B}_{2}$ can be obtained either by identifying $b_{1}$ and $b_{2}$, or by adding $\left(b_{1}, b_{2}\right)$ or $\left(b_{2}, b_{1}\right)$ to some relations of $\mathfrak{B}_{1} \cup \mathfrak{B}_{2}$. This can also be done in time exponential in the size of $\Phi$ because only single-exponentially many structures $\mathfrak{C}$ need to be checked. In sum, the existence of a counterexample can be tested in NEXPTIME, which is what we had to show.

## A. 2 Proof of Lemma 7

- Lemma 7. Let $\Phi$ be an equality-free universal Horn sentence over a relational signature $\tau$. Then the following are equivalent:

1. $\mathrm{fm}(\Phi)$ has the strong $A P$.
2. $\mathrm{fm}(\Phi)$ has the $A P$.
3. If $\phi(\bar{x}), \phi_{1}\left(\bar{x}, y_{1}\right)$, and $\phi_{2}\left(\bar{x}, y_{2}\right)$ are equality-free conjunctions of atomic formulas, where $y_{1}$ and $y_{2}$ are distinct variables not contained in $\bar{x}$, such that, for both $i \in\{1,2\}$, every atom in $\phi_{i}\left(\bar{x}, y_{i}\right)$ contains the variable $y_{i}$ and $\phi(\bar{x}) \wedge \phi_{i}\left(\bar{x}, y_{i}\right) \leq_{\Phi} \phi(\bar{x})$, then $\phi(\bar{x}) \wedge$ $\phi_{1}\left(\bar{x}, y_{1}\right) \wedge \phi_{2}\left(\bar{x}, y_{2}\right) \leq_{\Phi} \phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right)$.

Proof. " $(1) \Rightarrow(2)$ " This direction is trivial.
$"(2) \Rightarrow(3) "$ Let $\phi(\bar{x}), \phi_{1}\left(\bar{x}, y_{1}\right)$, and $\phi_{2}\left(\bar{x}, y_{2}\right)$ be as in item (3). Let $\Psi(\bar{x}), \Psi_{1}\left(\bar{x}, y_{1}\right)$, and $\Psi_{2}\left(\bar{x}, y_{2}\right)$ be the conjunctions of all $R$-atoms for $R \in \tau$ implied by $\Phi \wedge \phi(\bar{x}), \Phi \wedge \phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right)$, and $\Phi \wedge \phi(\bar{x}) \wedge \phi_{2}\left(\bar{x}, y_{2}\right)$, respectively. If $\Phi \wedge \Psi_{1}\left(\bar{x}, y_{1}\right)$ or $\Phi \wedge \Psi_{2}\left(\bar{x}, y_{2}\right)$ is unsatisfiable, then $\Phi \wedge \Psi(\bar{x})$ is unsatisfiable by the assumption and we are done. So suppose that both are formulas are satisfiable. Define $\mathfrak{B}_{1}$ and $\mathfrak{B}_{2}$ as the structures whose domains consist of the variables $\left\{y_{1}, \bar{x}[1], \ldots\right\}$ and $\left\{y_{2}, \bar{x}[1], \ldots\right\}$, respectively, and where $\bar{z}$ is a tuple of a relation for $R \in \tau$ if the conjunct $R(\bar{z})$ is contained in $\Psi_{1}$ or $\Psi_{2}$, respectively. Since we have $\phi(\bar{x}) \wedge \phi_{i}\left(\bar{x}, y_{i}\right) \leq_{\Phi} \phi(\bar{x})$ for both $i \in\{1,2\}$, the induced substructures of $\mathfrak{B}_{1}$ and $\mathfrak{B}_{2}$ on $B_{1} \cap B_{2}$ coincide. Note that, by construction, $\mathfrak{B}_{1}$ and $\mathfrak{B}_{2}$ satisfy every Horn clause in $\Phi$. Since $\Phi$ is universal Horn, this implies that $\mathfrak{B}_{1}, \mathfrak{B}_{2} \in \mathrm{fm}(\Phi)$. Since $\mathrm{fm}(\Phi)$ has the AP, there exists $\mathfrak{C} \in \operatorname{fm}(\Phi)$ together with embeddings $f_{i}: \mathfrak{B}_{i} \hookrightarrow \mathfrak{C}$ for both $i \in\{1,2\}$ such that $\left.f_{1}\right|_{B_{1} \cap B_{2}}=\left.f_{2}\right|_{B_{1} \cap B_{2}}$. By the construction of $\mathfrak{B}_{1}$ and $\mathfrak{B}_{2}$, it follows that $\Phi \mid \neq$ $\forall \bar{x}, y_{1}, y_{2}\left(\phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right) \wedge \phi_{2}\left(\bar{x}, y_{2}\right) \Rightarrow \perp\right)$. Let $\chi\left(\bar{x}, y_{1}\right)$ be an atomic $\tau$-formula other than equality such that $\Phi \models \forall \bar{x}, y_{1}, y_{2}\left(\phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right) \wedge \phi_{2}\left(\bar{x}, y_{2}\right) \Rightarrow \chi\left(\bar{x}, y_{1}\right)\right)$. By the construction of $\mathfrak{B}_{1}$ and $\mathfrak{B}_{2}$, and because $f_{1}$ and $f_{2}$ are homomorphisms, there exist a tuple $\bar{z}$ over $B_{1}$ such that $\mathfrak{C} \models \chi\left(f_{1}(\bar{z})\right)$. Since $f_{1}$ is an embedding, we must also have $\mathfrak{B}_{1} \models \chi(\bar{z})$. Thus, by the construction of $\mathfrak{B}_{1}$ and $\mathfrak{B}_{2}$, it follows that $\Phi \models \forall \bar{x}, y_{1}\left(\phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right) \Rightarrow \chi\left(\bar{x}, y_{1}\right)\right)$.
" $(3) \Rightarrow(1)$ " Let $\mathfrak{B}_{1}, \mathfrak{B}_{2} \in \operatorname{fm}(\Phi)$ be an arbitrary one-point amalgamation diagram. Let $y_{1}$ and $y_{2}$ be the unique elements contained in $B_{1} \backslash B_{2}$ and $B_{2} \backslash B_{1}$, respectively. We construct a structure $\mathfrak{C} \in \operatorname{fm}(\Phi)$ with embeddings $f_{i}: \mathfrak{B}_{i} \hookrightarrow \mathfrak{C}$ for both $i \in\{1,2\}$ as follows. Let $\bar{x}$ be a tuple of variables representing the elements of $B_{1} \cap B_{2}$ in some order, and let $\phi(\bar{x})$ be the conjunction of all $R$-atoms for $R \in \tau$ which hold in $\mathfrak{B}_{1} \cap \mathfrak{B}_{2}$. Moreover, for
both $i \in\{1,2\}$, let $\phi_{i}\left(\bar{x}, y_{i}\right)$ be the conjunction of all $R$-atoms for $R \in \tau$ which contain the variable $y_{i}$ and hold in $\mathfrak{B}_{i}$. By construction, for both $i \in\{1,2\}$, we have $\phi(\bar{x}) \wedge$ $\phi_{i}\left(\bar{x}, y_{i}\right) \leq_{\Phi} \phi(\bar{x})$ because $\mathfrak{B}_{i} \models \Phi$. Let $\Psi\left(\bar{x}, y_{1}, y_{2}\right)$ be the conjunction of all $R$-atoms for $R \in \tau$ implied by $\Phi \wedge \phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right) \wedge \phi_{2}\left(\bar{x}, y_{2}\right)$. We claim that $\Phi \wedge \Psi$ is satisfiable: otherwise, $\Phi \models \forall \bar{x}, y_{1}, y_{2}\left(\phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right) \wedge \phi_{2}\left(\bar{x}, y_{2}\right) \Rightarrow \perp\right)$, and then item (3) implies that $\Phi \models \forall \bar{x}, y_{1}\left(\phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right) \Rightarrow \perp\right)$, which is impossible since $\mathfrak{B}_{1} \models \Phi$. Define $\mathfrak{C}$ as the structure with domain $\left\{y_{1}, y_{2}, \bar{x}[1], \ldots\right\}$ and such that $R^{\mathfrak{C}}$ contains a tuple $\bar{z}$ if and only if $\Psi$ contains the conjunct $R(\bar{z})$. For both $i \in\{1,2\}$, let $f_{i}$ be the identity map on $B_{i}$. By definition, we have $\left.f_{1}\right|_{B_{1} \cap B_{2}}=\left.f_{2}\right|_{B_{1} \cap B_{2}}$ and $f_{1}\left(B_{1}\right) \cap f_{2}\left(B_{2}\right)=f_{1}\left(B_{1} \cap B_{2}\right)=f_{2}\left(B_{1} \cap B_{2}\right)$. We claim that, for both $i \in\{1,2\}, f_{i}$ is an embedding from $\mathfrak{B}_{i}$ to $\mathfrak{C}$. It is clear from the construction of $\mathfrak{C}$ that $f_{i}$ is a homomorphism. Suppose for contradiction that there exists $R \in \tau$ and a tuple $\bar{z}$ over $B_{i}$ such that $\bar{z} \notin R^{\mathfrak{B}_{i}}$ while $f_{i}(\bar{z}) \in R^{\mathfrak{C}}$. For the sake of notation, we assume that $i=1$; the case that $i=2$ can be shown analogously. Note that the construction of $\mathfrak{C}$ implies that $\Phi \models \forall \bar{x}, y_{1}, y_{2}\left(\phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right) \wedge \phi_{2}\left(\bar{x}, y_{2}\right) \Rightarrow R(\bar{z})\right)$. Then item (3) implies that $\Phi \models \forall \bar{x}, y_{1}\left(\phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right) \Rightarrow R(\bar{z})\right)$, a contradiction to $\mathfrak{B}_{1} \in \operatorname{fm}(\Phi)$. Thus, $f_{i}$ is an embedding from $\mathfrak{B}_{i}$ to $\mathfrak{C}$. This concludes the proof of the strong AP restricted to one-point amalgamation diagrams. Now the statement follows similarly as in Proposition 2.

## A. 3 Proof of Theorem 4

- Theorem 4. Given a universal Horn sentence $\Phi$ over a finite relational signature that is binary except for one ternary symbol, the question whether $\mathrm{fm}(\Phi)$ has the AP is PSPACEhard.

Proof. We reduce from the universality problem for left-regular grammars, which is known to be PSPACE-complete [3]. Let $\mathscr{G}=(N, \Sigma, P, S)$ be a left-regular grammar.

First, consider the Horn sentence $\Phi_{1}$ over the signature $\tau_{1}=\{L, I, T, E\} \cup\left\{R_{a} \mid a \in\right.$ $\Sigma \cup N\}$ in prenex normal form whose quantifier-free part consists of the Horn clause

$$
\begin{equation*}
I\left(x_{1}\right) \wedge R_{S}\left(x_{1}, x_{2}\right) \wedge T\left(x_{2}\right) \Rightarrow \perp \tag{4}
\end{equation*}
$$

as well as

$$
\begin{array}{rlr}
L\left(y_{1}\right) \wedge I\left(y_{1}\right) \wedge E\left(y_{1}, x_{2}\right) & \wedge R_{B}\left(y_{1}, x_{1}\right) \wedge R_{a}\left(x_{1}, x_{2}\right) & \Rightarrow R_{A}\left(y_{1}, x_{2}\right), \quad(A \rightarrow B a \in P) \\
L\left(y_{1}\right) \wedge I\left(y_{1}\right) \wedge R_{a}\left(y_{1}, x_{1}\right) & \Rightarrow R_{A}\left(y_{1}, x_{1}\right) . & (A \rightarrow a \in P)
\end{array}
$$

The proof of the following claim is straightforward and left to the reader.
$\triangleright$ Claim 15. For every $w=a_{1} \ldots a_{n} \in \Sigma^{+}$and $A \in N$, we have $A \rightarrow_{\mathscr{G}}^{*} w$ if and only if

$$
\left.\Phi_{1} \models \forall x_{1}, \ldots, x_{n}, y_{1}\left(\begin{array}{c}
L\left(y_{1}\right) \wedge I\left(y_{1}\right) \wedge R_{a_{1}}\left(y_{1}, x_{1}\right)  \tag{5}\\
\wedge \bigwedge_{i \in[n-1]} R_{a_{i}}\left(x_{i}, x_{i+1}\right) \wedge E\left(y_{1}, x_{i+1}\right)
\end{array}\right\} \Rightarrow R_{A}\left(y_{1}, x_{n}\right)\right)
$$

Secondly, consider the Horn sentence $\Phi_{2}$ over the signature $\tau_{2}=\{L, R, I, T, E, Q\} \cup\left\{R_{a} \mid\right.$ $a \in \Sigma\}$ defined as the universally quantified conjunction of all Horn clauses of the form

$$
\begin{align*}
L\left(y_{1}\right) \wedge R\left(y_{2}\right) \wedge I\left(y_{1}\right) \wedge R_{a}\left(y_{1}, x_{1}\right) \wedge E\left(y_{2}, x_{1}\right) & \Rightarrow Q\left(y_{1}, y_{2}, x_{1}\right),  \tag{6}\\
Q\left(y_{1}, y_{2}, x_{1}\right) \wedge R_{a}\left(x_{1}, x_{2}\right) \wedge E\left(y_{1}, x_{2}\right) \wedge E\left(y_{2}, x_{2}\right) & \Rightarrow Q\left(y_{1}, y_{2}, x_{2}\right)  \tag{7}\\
Q\left(y_{1}, y_{2}, x_{1}\right) \wedge T\left(x_{1}\right) & \Rightarrow \perp \tag{8}
\end{align*}
$$

The proof of the following claim is also straightforward and left to the reader.

Figure 2 An illustration of the AP-counterexamples from Claim 16.
$\triangleright$ Claim 16. Let $\phi(\bar{x})$ be a conjunction of $(\tau \backslash\{Q\})$-atoms. Then $\Phi_{2} \models \forall \bar{x}(\phi(\bar{x}) \Rightarrow \perp)$ if and only if there exists $a_{1} \ldots a_{n} \in \Sigma^{+}$such that $\phi$ contains the premise of

$$
\left.\begin{array}{l}
R_{a_{1}}\left(y_{1}, x_{1}\right) \wedge \bigwedge_{i \in[n-1]} R_{a_{i+1}}\left(x_{i}, x_{i+1}\right) \wedge E\left(y_{1}, x_{i+1}\right)  \tag{9}\\
\wedge I\left(y_{1}\right) \wedge T\left(x_{n}\right) \wedge \bigwedge_{i \in[n]} E\left(y_{2}, x_{i}\right) \wedge L\left(y_{1}\right) \wedge R\left(y_{2}\right)
\end{array}\right\} \Rightarrow \perp
$$

as a subformula modulo renaming of the variables (see Figure 2).
We set $\Phi:=\Phi_{1} \wedge \Phi_{2}$, and show that $\mathrm{fm}(\Phi)$ has the AP if and only if $L(\mathscr{G})=\Sigma^{+}$. We remark that the roles of $L$ and $I$ are (coincidentally) identical in our construction, but we keep both symbols for the sake of staying consistent with the previous proofs.
" $\Rightarrow$ " Suppose that $\mathrm{fm}(\Phi)$ has the AP. Let $a_{1} \ldots a_{n} \in \Sigma^{+}$be arbitrary. Consider the formulas $\phi\left(x_{1}, \ldots, x_{n}\right), \phi_{1}\left(x_{1}, \ldots, x_{n}, y_{1}\right)$, and $\phi_{2}\left(x_{1}, \ldots, x_{n}, y_{2}\right)$ given by

$$
\begin{aligned}
\phi & :=T\left(x_{n}\right) \wedge \bigwedge_{i \in[n-1]} R_{a_{i+1}}\left(x_{i}, x_{i+1}\right), \\
\phi_{1} & :=L\left(y_{1}\right) \wedge I\left(y_{1}\right) \wedge R_{a_{1}}\left(y_{1}, x_{1}\right) \wedge \bigwedge_{i \in[n-1]} E\left(y_{1}, x_{i+1}\right), \\
\text { and } \quad \phi_{2} & :=R\left(y_{2}\right) \wedge \bigwedge_{i \in[n]} E\left(y_{2}, x_{i}\right) .
\end{aligned}
$$

By Claim 16, we have

$$
\begin{equation*}
\Phi_{2} \models \forall x_{1}, \ldots, x_{n}, y_{1}, y_{2}\left(\phi \wedge \phi_{1} \wedge \phi_{2} \Rightarrow \perp\right) . \tag{10}
\end{equation*}
$$

We claim that $\Phi \wedge \phi \wedge \phi_{2}$ is satisfiable and $\phi \wedge \phi_{2} \leq_{\Phi} \phi$. Let $\chi\left(x_{1}, \ldots, x_{n}\right)$ be an atomic $\tau$-formula other than equality such that $\Phi \models \forall x_{1}, \ldots, x_{n}, y_{2}\left(\phi \wedge \phi_{2} \Rightarrow \chi\right)$. Note that all Horn clauses in $\Phi$ contain an $\{I, Q\}$-atom in their premise while $\phi \wedge \phi_{2}$ contains no $\{I, Q\}$ atoms. As a consequence, $\phi \wedge \phi_{2} \Rightarrow \chi$ must be a tautology, i.e., $\chi$ is a subformula of $\phi \wedge \phi_{2}$. In particular, $\chi$ cannot be of the form $\perp$. Since every atom in $\phi_{2}$ contains the variable $y_{2}$ while $\chi$ does not, $\chi$ is a subformula of $\phi$. It follows that $\Phi \models \forall x_{1}, \ldots, x_{n}(\phi \Rightarrow \chi)$. Since $\chi$ was chosen arbitrarily, this confirms our claim.

Since $\mathrm{fm}(\Phi)$ has the AP and we already have $\phi \wedge \phi_{2} \leq_{\Phi} \phi$, by Lemma 7, it cannot be the case that $\phi \wedge \phi_{1} \leq_{\Phi} \phi$. Otherwise, (10) would lead to a contradiction to the satisfiability of $\Phi \wedge \phi \wedge \phi_{2}$ via Lemma 7. Thus, there must exist an atomic formula $\chi\left(x_{1}, \ldots, x_{n}\right)$ other than equality such that

$$
\begin{equation*}
\Phi \models \forall x_{1}, \ldots, x_{n}, y_{1}\left(\phi \wedge \phi_{1} \Rightarrow \chi\right) \quad \text { and } \quad \Phi \mid \vDash \forall x_{1}, \ldots, x_{n}(\phi \Rightarrow \chi) . \tag{11}
\end{equation*}
$$

By Theorem 8, we have $\Phi \vdash \forall x_{1}, \ldots, x_{n}, y_{1}\left(\phi \wedge \phi_{1} \Rightarrow \chi\right)$. Clearly, by (11), $\phi \wedge \phi_{1} \Rightarrow \chi$ is not a tautology because every atom in $\phi_{1}$ contains the variable $y_{1}$ while $\chi$ does not. Thus,
$\phi \wedge \phi_{1} \Rightarrow \chi$ is a weakening of a Horn clause $\psi$ that has an SLD-derivation $\psi_{0}, \ldots \psi_{s}=\psi$ from $\Phi$ modulo renaming variables. Since every Horn clause in $\Phi_{2}$ contains an $\{Q, R\}$-atom in its premise while Horn clauses in $\Phi_{1}$, as well as $\phi \wedge \phi_{1}$, do not contain any $\{Q, R\}$-atoms, $\Phi_{2}$ cannot contribute anything during the SLD-derivation step. Therefore, the SLD-derivation $\psi_{0}, \ldots \psi_{s}=\psi$ is from $\Phi_{1}$. Note that, if a variable appears in an $I$-atom in the premise of a Horn clause from $\Phi_{1}$ whose conclusion is not $\perp$, then this variable also appears in an atom from the conclusion. Moreover, no Horn clause from $\Phi_{1}$ contains an $I$-atom in its conclusion. Since $y_{1}$ is the only variable which appears in an $I$-atom in $\phi \wedge \phi_{1}$ and $\chi$ does not contain the variable $y_{1}, \psi_{0}$ must be of the form (4). Thus, we have that

$$
\begin{equation*}
\Phi_{1} \vdash \forall x_{1}, \ldots, x_{n}, y_{1}\left(\phi \wedge \phi_{1} \Rightarrow \perp\right) \tag{12}
\end{equation*}
$$

Let $\phi^{\prime}$ be the conjunction of atomic formulas obtained from $\phi$ by removing the atom $T\left(x_{n}\right)$. Note that $x_{n}$ is the only variable which appears in a $T$-atom in $\phi \wedge \phi_{1}$ and no Horn clause from $\Phi_{1}$ contains an $T$-atom in its conclusion. Since $\psi_{0}$ is of the form (4), we must have

$$
\Phi_{1} \models \forall x_{1}, \ldots, x_{n}, y_{1}\left(\phi^{\prime} \wedge \phi_{1} \Rightarrow R_{S}\left(y_{1}, x_{n}\right)\right)
$$

otherwise a counterexample to (12) can be easily constructed. But then it follows from Claim 15 that $a_{1} \ldots a_{n} \in L(\mathscr{G})$ and we are done.
$" \Leftarrow$ " We prove the contrapositive. We assume that $\mathrm{fm}(\Phi)$ does not have the AP. Then there exists a counterexample to Lemma 7, i.e., there exists a Horn clause $\psi$ of the form $\phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right) \wedge \phi_{2}\left(\bar{x}, y_{2}\right) \Rightarrow \chi$, where $\phi, \phi_{1}$, and $\phi_{2}$ satisfy the prerequisites of Lemma 7 and $\chi\left(\bar{x}, y_{1}\right)$ is an atomic $\tau$-formula other than equality, such that

$$
\begin{align*}
& \Phi \models \forall \bar{x}, y_{1}, y_{2}\left(\phi \wedge \phi_{1} \wedge \phi_{2} \Rightarrow \chi\right)  \tag{13}\\
\text { and } \quad \Phi^{\prime} & \not \models \forall \bar{x}, y_{1}\left(\phi \wedge \phi_{1} \Rightarrow \chi\right) . \tag{14}
\end{align*}
$$

We choose $\psi$ minimal with respect to the number of its atomic subformulas.
Our proof strategy is as follows. First we show that $\psi$ encodes a single word $w \in \Sigma^{+}$ in the sense of Claim 16. Then we show that the word $w$ may not be contained in $L(\mathscr{G})$, because otherwise a part of the counterexample would encode $w$ in the sense of Claim 15 which would lead to a contradiction.
$\triangleright$ Claim 17. The formula $\Phi \wedge \phi(\bar{x}) \wedge \phi_{i}\left(\bar{x}, y_{i}\right)$ is satisfiable for both $i \in\{1,2\}$.
Proof. Suppose for contradiction that $\Phi \models \forall x_{1}, \ldots, x_{n}, y_{i}\left(\phi \wedge \phi_{i} \Rightarrow \perp\right)$ for some $i \in\{1,2\}$. Since the conclusion of $\phi \wedge \phi_{i} \Rightarrow \perp$ does not contain the variable $y_{i}$ and $\phi(\bar{x}) \wedge \phi_{i}\left(\bar{x}, y_{i}\right) \leq_{\Phi}$ $\phi(\bar{x})$ for both $i \in[2]$, it follows that $\Phi \models \forall \bar{x}(\phi(\bar{x}) \Rightarrow \perp)$. But this yields a contradiction to (14). Thus, the statement holds.
$\triangleright$ Claim 18. The formula $\psi$

- is not a tautology,
- has an SLD-deduction from $\Phi_{2}$,
- only contains $\tau_{2}$-atoms.

Proof. First, we claim that $\Phi_{1} \vdash \psi$ or $\Phi_{2} \vdash \psi$. By Theorem 8, we have $\Phi \vdash \psi$. Note that $\chi\left(\bar{x}, y_{1}\right)$ cannot be a subformula of $\phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right)$, by (14). Also note that $\chi\left(\bar{x}, y_{1}\right)$ cannot be a subformula of $\phi_{2}\left(\bar{x}, y_{2}\right)$, because every atom in $\phi_{2}\left(\bar{x}, y_{2}\right)$ contains the variable $y_{2}$. Hence, $\chi\left(\bar{x}, y_{1}\right)$ is not a subformula of $\phi(\bar{x}) \wedge \phi_{1}\left(\bar{x}, y_{1}\right) \wedge \phi_{2}\left(\bar{x}, y_{2}\right)$, i.e., $\psi$ is not a tautology.

Thus, $\psi$ is a weakening of a Horn clause $\psi^{\prime}$ which has an SLD-derivation $\psi_{0}^{\prime}, \ldots, \psi_{s}^{\prime}=\psi^{\prime}$ from $\Phi$ modulo renaming variables. Note that the Horn clauses in $\Phi$ have the property that, depending on whether they come from $\Phi_{1}$ or from $\Phi_{2}$, they either contain no $Q$-atoms or no $R_{A}$-atoms for $A \in N$, respectively. This applies in particular to $\psi_{0}^{\prime}$ which is a conjunct of $\Phi$. Since the conclusion of each Horn clause in $\Phi_{1}$ is an $R_{A}$-atom for $A \in N$ and the conclusion of each Horn clause in $\Phi_{2}$ is a $Q$-atom, the property of $\psi_{0}^{\prime}$ from above propagates inductively to every $\psi_{i}^{\prime}$ for $i \in[k]$. But this means that $\psi^{\prime}$ has an SLD-derivation from $\Phi_{1}$ or from $\Phi_{2}$. Hence, $\psi$ has an SLD-deduction from $\Phi_{1}$ or from $\Phi_{2}$, which concludes the claim.

Next, we claim that $\Phi_{2} \vdash \psi$. Suppose, on the contrary, that $\Phi_{1} \vdash \psi$. Let $\phi^{\prime}, \phi_{1}^{\prime}$, and $\phi_{2}^{\prime}$ be the formulas obtained from $\phi, \phi_{1}$, and $\phi_{2}$, respectively, by removing all $Q$-atoms. Since $\Phi_{1} \vdash \psi$, the SLD-derivation sequence $\psi_{0}^{\prime}, \ldots, \psi_{s}^{\prime}$ from the first paragraph contains no $Q$-atoms. Thus, all $Q$-atoms occurring in $\psi$ come from the weakening step, which means that

$$
\begin{equation*}
\Phi_{1} \vdash \forall \bar{x}, y_{1}, y_{2}\left(\phi^{\prime} \wedge \phi_{1}^{\prime} \wedge \phi_{2}^{\prime} \Rightarrow \chi\right) \tag{15}
\end{equation*}
$$

We show that, for both $i \in[2]$,

$$
\begin{equation*}
\phi^{\prime}(\bar{x}) \wedge \phi_{i}^{\prime}\left(\bar{x}, y_{i}\right) \leq_{\Phi_{1}} \phi^{\prime}(\bar{x}) \tag{16}
\end{equation*}
$$

Let $\eta(\bar{x})$ be an atomic $\tau_{1}$-formula other than equality such that $\Phi_{1} \models \forall \bar{x}, y_{i}\left(\phi^{\prime} \wedge \phi_{i}^{\prime} \Rightarrow \eta\right)$ for some $i \in[2]$. Since $\phi(\bar{x}) \wedge \phi_{i}\left(\bar{x}, y_{i}\right) \leq_{\Phi} \phi(\bar{x})$ for both $i \in[2]$, we have $\Phi \models \forall \bar{x}(\phi \Rightarrow \eta)$. Clearly, for both $i \in[2], \eta$ cannot be a subformula of $\phi_{i}$ because every atom in $\phi_{i}$ contains the variable $y_{i}$. If $\eta$ is a subformula of $\phi$, then trivially $\Phi_{1} \models \forall \bar{x}\left(\phi^{\prime} \Rightarrow \eta\right)$ and the claim holds. So suppose that this is not the case. By Theorem 8, we have $\Phi \vdash \forall \bar{x}(\phi \Rightarrow \eta)$. Since $\phi \Rightarrow \eta$ is not a tautology, it is a weakening of a Horn clause which has an SLD-derivation from $\Phi$ modulo renaming variables. Since $\Phi \wedge \phi$ is satisfiable by Claim 17, $\eta$ neither is of the form $\perp$ nor was it obtained by replacing $\perp$ with a different $\tau_{1}$-atom during the weakening step. Consequently, $\eta$ can only be an $R_{A}$-atom for some $A \in N$ because other symbols from $\tau_{1}$ do not appear in the conclusion of any Horn clause in $\Phi$. But then, since $R_{A}$-atoms only appear in the conclusion of Horn clauses from $\Phi_{1}$, and no Horn clause from $\Phi_{2}$ contains an atom in its conclusion that would appear in the premise of a Horn clause from $\Phi_{1}$, it must be the case that $\Phi_{1} \vdash \forall \bar{x}(\phi \Rightarrow \eta)$. Consequently, $\Phi_{1} \vdash \forall \bar{x}\left(\phi^{\prime} \Rightarrow \eta\right)$ because $\{Q, R\}$-atoms do not appear in any Horn clause from $\Phi_{1}$. Since $\eta$ was chosen arbitrarily, we conclude that (16) indeed holds. Now we come back to the SLD-derivation sequence $\psi_{0}^{\prime}, \ldots, \psi_{s}^{\prime}$. Since $\psi_{0}^{\prime}$ is a Horn clause from $\Phi_{1}$, it follows from the minimality assumption for $\psi$ that either $\chi$ is an $R_{A}$-atom for some $A \in N$, or $\chi$ equals $\perp$. In both cases, (16), (15), and (14) witness that $\mathrm{fm}\left(\Phi_{1}\right)$ does not have AP through an application of Lemma 7. But this is in contradiction to the fact that $\mathrm{fm}\left(\Phi_{1}\right)$ is preserved by unions because $\Phi_{1}$ is complete. Thus, $\Phi_{1} \vdash \psi$ does not hold, and $\Phi_{2} \vdash \psi$ holds instead.

Since we have $\Phi_{2} \vdash \psi$, the premise $\phi \wedge \phi_{1} \wedge \phi_{2}$ of $\psi$ can only contain symbols from $\tau_{2}$, otherwise we could remove all $\left(\tau_{1} \backslash \tau_{2}\right)$-atoms and get a contradiction to the minimality of $\psi$. Since $\psi_{0}^{\prime}$ is a Horn clause from $\Phi_{2}$, it also follows from the minimality assumption for $\psi$ that either $\chi$ is an $Q$-atom, or $\chi$ is $\perp$. Thus, $\psi$ only contains symbols from $\tau_{2}$.

Let $\psi^{\prime}$ be a Horn clause such that $\psi$ is a weakening of $\psi^{\prime}$ and there is an SLD-derivation $\psi_{0}^{\prime}, \ldots, \psi_{s}^{\prime}=\psi^{\prime}$ from $\Phi_{2}$ modulo renaming variables. Recall that, since $\psi$ is a weakening of $\psi^{\prime}$, every atom from the premise of $\psi^{\prime}$ also appears in the premise of $\psi$.
$\triangleright$ Claim 19. $\psi^{\prime}$ does not contain any $Q$-atoms and its conclusion equals $\perp$.

Proof. Note that, by the construction of $\Phi_{2}$, for every $i \in[k]$, if there exist variables $z_{1}, z_{2}$ in $\psi_{i-1}^{\prime}$ such that
every $Q$-atom contains $z_{1}$ in its first and $z_{2}$ in its second argument, respectively,
then $\psi_{i}^{\prime}$ also satisfies (17) for the same variables $z_{1}, z_{2}$ up to renaming. Since every possible choice of $\psi_{0}^{\prime}$ from $\Phi_{2}$ initially satisfies (17) for some variables, it follows via induction that (17) must hold for $\psi^{\prime}=\psi_{s}^{\prime}$ for some variables. Also note that (6) is the only Horn clause in $\Phi_{2}$ that is not complete, but the incompleteness is only due to one missing edge in the Gaifman graph between the two distinguished variables satisfying (17) for (6).

We claim that $\left\{z_{1}, z_{2}\right\}=\left\{y_{1}, y_{2}\right\}$ holds for the pair $z_{1}, z_{2}$ satisfying (17) for $\psi^{\prime}$. Suppose, on the contrary, that both $z_{1}$ and $z_{2}$ are among $\bar{x}, y_{1}$ or $\bar{x}, y_{2}$. For every $i \in[k], \psi_{i}^{\prime}$ is a resolvent of $\psi_{i-1}^{\prime}$ and a Horn clause from $\Phi_{2}$ which is almost complete except for one missing edge in the Gaifman graph between a pair of variables which must be substituted for the pair $\left(z_{1}, z_{2}\right)$ satisfying (17) for $\psi_{i-1}^{\prime}$. Since the variables $y_{1}$ and $y_{2}$ do not appear together in any atom in $\psi^{\prime}$ and $\left\{z_{1}, z_{2}\right\} \neq\left\{y_{1}, y_{2}\right\}$, they also do not appear together in any atom during the SLD-derivation. Then it follows from the fact that $\phi, \phi_{1}$, and $\phi_{2}$ satisfy the prerequisites of Lemma 7 that we already have $\Phi_{2} \vdash \forall \bar{x}, y_{1}\left(\phi \wedge \phi_{1} \Rightarrow \chi\right)$, a contradiction to (14). Therefore, $\left\{z_{1}, z_{2}\right\}=\left\{y_{1}, y_{2}\right\}$.

We claim that $\psi_{0}^{\prime}$ is of the form (8). Otherwise, $\psi_{0}^{\prime}$ is of the form (6) or (7), in which case the conclusion of $\psi^{\prime}$ is a $Q$-atom. But then, since $z_{1}, z_{2}$ with $\left\{z_{1}, z_{2}\right\}=\left\{y_{1}, y_{2}\right\}$ satisfy (17) for $\psi^{\prime}$, the conclusion of $\psi^{\prime}$ would be an atom containing both variables $y_{1}$ and $y_{2}$. This leads to a contradiction to (13) where we assume that the conclusion of $\psi^{\prime}$ may only contain variables from $\bar{x}, y_{1}$. The claim implies that the conclusion of $\psi^{\prime}$ equals $\perp$. Hence, $\psi^{\prime}$ does not contain any $Q$-atoms at all.

By Claim 16, there exists $a_{1}, \ldots, a_{n} \in \Sigma^{+}$such that the premise of $\psi^{\prime}$ contains the premise of (5) as a subformula modulo renaming and indentifying variables. Since $\phi, \phi_{1}$, and $\phi_{2}$ satisfy the prerequisites of Lemma 7, it must be the case that

- $\phi(\bar{x})$ has $T\left(x_{n}\right) \wedge \bigwedge_{i \in[n-1]} R_{a_{i+1}}\left(x_{i}, x_{i+1}\right)$ as a subformula,
- $\phi_{1}\left(\bar{x}, y_{1}\right)$ has $L\left(y_{1}\right) \wedge I\left(y_{1}\right) \wedge R_{a_{1}}\left(y_{1}, x_{1}\right) \wedge \bigwedge_{i \in[n-1]} E\left(y_{1}, x_{i+1}\right)$ as a subformula, and
- $\phi_{2}\left(\bar{x}, y_{2}\right)$ has $R\left(y_{2}\right) \wedge \bigwedge_{i \in[n]} E\left(y_{2}, x_{i}\right)$ as a subformula,
where the variables need not all be distinct and the roles of $\phi_{1}$ and $\phi_{2}$ might be swapped. Otherwise, we get a contradiction to Claim 17. Note that, if $L(\mathscr{G})=\Sigma^{+}$, then Claim 15 together with (4) implies that

$$
\begin{equation*}
\Phi_{1} \models \forall x_{1}, \ldots, x_{n+1}\left(\phi \wedge \phi_{1} \Rightarrow \perp\right) . \tag{18}
\end{equation*}
$$

If some variables among $x_{1}, \ldots, x_{n}$ are identified in $\phi \wedge \phi_{1} \wedge \phi_{2}$, then we still have (18) even if we perform the same identification of variables. But then we get a contradiction to Claim 17 . Thus, $L(\mathscr{G}) \neq \Sigma^{+}$.

We have thus found a reduction from the PSPACE-hard universality problem for $\mathscr{G}$ to the decidability problem of the AP for $\operatorname{fm}(\Phi)$; note that $\Phi$ is universal Horn and can be computed from $\mathscr{G}$ in polynomial time.

## A. 4 Proof of Lemma 14

- Lemma 14. Let $\mathscr{G}$ be a context-free grammar. Then the following are equivalent:

1. $L(\mathscr{G})$ is regular.
2. $\Phi_{\mathscr{G}}$ is equivalent to monadic Datalog sentence.
3. $\Phi_{G}$ is equivalent to a GMSNP sentence.
4. $\mathrm{fm}\left(\Phi_{G}\right)$ is the CSP of a finite structure.
5. $\mathrm{fm}\left(\Phi_{\mathscr{G}}\right)$ is the CSP of an $\omega$-categorical structure.
6. $\mathrm{fm}\left(\Phi_{\mathscr{G}}\right)$ is the age of a reduct of a finitely bounded homogeneous Ramsey structure.
7. $\mathrm{fm}\left(\Phi_{\mathscr{G}}\right)$ is the age of an $\omega$-categorical structure.
8. $\mathrm{fm}\left(\Phi_{\mathscr{G}}\right)$ is finitely bounded homogenizable.

Before we can prove the lemma, we need to introduce some additional terminology and one model-theoretic result from [16].

A deterministic finite automaton (DFA) is a 5 -tuple $\mathscr{A}=\left(Q, \Sigma, \delta, q_{0}, F\right)$ where $Q$ is a finite set of states, $\Sigma$ is a finite set of input symbols, $\delta: Q \times \Sigma \rightarrow Q$ is a transition function, $q_{0} \in Q$ is a distinguished starting state, and $F \subseteq Q$ is a distinguished set of final states. The language of $\mathscr{A}$ is $L(\mathscr{A}):=\left\{a_{1} \ldots a_{n} \in \Sigma^{+} \mid \delta\left(a_{n}, \ldots \delta\left(a_{2}, \delta\left(a_{1}, q_{0}\right)\right) \ldots\right) \in F\right\}$. Note that, as in the case of CFGs, the empty word $\epsilon$ can never be an element of $L(\mathscr{A})$ according to the present definition.

Let $\Sigma$ be a finite set of symbols and $L$ a subset of $\Sigma^{+}$. The Myhill-Nerode equivalence relation on $\Sigma^{*}$, denoted by $\sim_{L}$, is defined by $w_{1} \sim_{L} w_{2}$ if there is no $w \in \Sigma^{*}$ such that $\left|\left\{w_{1} w, w_{2} w\right\} \cap L\right|=1$. The following correspondence is well-known.

- Theorem 20 (Myhill-Nerode). For every finite set $\Sigma$ and every $L \subseteq \Sigma^{+}$, the following are equivalent:
- $L$ is regular;
- $L$ is accepted by a DFA;
- $\sim_{L}$ has finitely many classes.
- Example 21. $\left\{a^{m} b^{n} \mid m, n \geq 1\right\}$ is regular while $\left\{a^{n} b^{n} \mid n \geq 1\right\}$ is not.

Let $\mathscr{A}=\left(Q, \Sigma, \delta, q_{0}, F\right)$ be a DFA. The signature $\tau_{\Sigma}$ is defined as before, and the signature $\tau_{Q}$ consists of the unary symbols $R_{q}$ for every $q \in Q$ that is reachable from $q_{0}$, i.e., there exists a word $a_{1} \ldots a_{n} \in \Sigma^{+}$such that $q=\delta\left(a_{n}, \ldots \delta\left(a_{2}, \delta\left(a_{1}, q_{0}\right)\right) \ldots\right)$. Note that $q_{0}$ is not necessarily reachable from itself. Let $\bar{\Phi}_{\mathscr{A}}$ be the universal Horn sentence over the signature $\tau_{\Sigma} \cup \tau_{Q}$ whose quantifier-free part contains: for every $a \in \Sigma$, the Horn clause

$$
I\left(x_{1}\right) \wedge R_{a}\left(x_{1}, x_{2}\right) \Rightarrow R_{\delta\left(q_{0}, a\right)}\left(x_{2}\right)
$$

for every $(q, a) \in Q \times \Sigma$ such that $q$ is reachable from $q_{0}$, the Horn clause

$$
R_{q}\left(x_{1}\right) \wedge R_{a}\left(x_{1}, x_{2}\right) \Rightarrow R_{\delta(q, a)}\left(x_{2}\right)
$$

and, for every $q \in F$ that is reachable from $q_{0}$, the Horn clause

$$
R_{q}\left(x_{1}\right) \wedge T\left(x_{1}\right) \Rightarrow \perp
$$

Then $\Phi_{\mathscr{A}}$ is the connected monadic Datalog sentence obtained from $\bar{\Phi}_{\mathscr{A}}$ by existentially quantifying all symbols from $\tau_{Q}$ upfront. The following lemma can be proved similarly as Lemma 13, and its proof is omitted.

- Lemma 22. For a $\tau_{\Sigma \text {-structure }} \mathfrak{A}$, we have $\mathfrak{A} \models \Phi_{\mathscr{A}}$ if and only if, for every $w \in L(\mathscr{A})$,

$$
\mathfrak{A} \models \forall x_{1}, \ldots, x_{|w|+1}\left(I\left(x_{1}\right) \wedge \phi_{w}\left(x_{1}, \ldots, x_{|w|+1}\right) \wedge T\left(x_{|w|+1}\right) \Rightarrow \perp\right) .
$$

To the following model-theoretic correspondence was essentially proved in [16].

- Theorem 23 ([16]). Every GMSNP sentence is equivalent to a finite disjunction of connected GMSNP sentences. If $\Phi$ is a connected GMSNP sentence, then there exists a reduct $\mathfrak{R}$ of a finitely bounded homogeneous Ramsey structure with $\mathrm{fm}(\Phi)=\operatorname{age}(\mathfrak{R})=\operatorname{CSP}(\mathfrak{R})$.

Proof of Theorem 23, second part only. The fact that every GMSNP sentence is equivalent to a finite disjunction of connected GMSNP sentences was proved in [16] in great detail, so we refer the reader there and start already with a connected GMSNP sentence.

Let $\Phi:=\exists X_{1}, \ldots, X_{n} \forall \bar{x} . \phi$ be an arbitrary connected GMSNP sentence and $\tau$ its signature. Set $\sigma:=\left\{X_{1}, \ldots, X_{n}\right\}$. We define two new signatures $\tau^{\prime}$ and $\sigma^{\prime}$ by introducing two new symbols $R^{+}$and $R^{-}$for every $R \in \tau \cup \sigma$. Then we obtain a new GMSNP sentence $\Phi^{\prime}:=\exists X_{1}^{+}, X_{1}^{-}, \ldots, X_{n}^{+}, X_{n}^{-} \forall \bar{x} . \phi^{\prime}$ over $\tau^{\prime}$ as follows. In every clause of $\phi$, we replace each negative atom $\neg R(\bar{x})$ the negative atom $\neg R^{+}(\bar{x})$ and each positive atom $R(\bar{x})$ with the negative atom $\neg R^{-}(\bar{x})$. The new GMSNP sentence is still connected, and additionally has the property that none of its clauses contains positive atoms. It follows that $\operatorname{fm}\left(\forall \bar{x} . \phi^{\prime}\right)$ is defined by forbidden homomorphic images from finitely many connected finite $\tau^{\prime} \cup \sigma^{\prime}$-structures. By Theorem 1.3 in [34], there exists a particular finitely bounded class $\mathcal{A}$ over a larger signature $\rho$ which has the AP and whose $\tau^{\prime} \cup \sigma^{\prime}$-reducts are precisely the members of $\operatorname{fm}\left(\forall \bar{x} . \phi^{\prime}\right)$. Let $<$ be a fresh binary symbol not contained in $\rho$. We define $\mathcal{R}$ as the class of all $\{<\} \cup \rho$ expansions of structures from $\mathcal{A}$ where $<$ interprets as a linear order. Clearly, $\mathcal{R}$ is still finitely bounded. By Theorem 2.11 in [33], $\mathcal{R}$ is a Ramsey class (see also Theorem A. 3 in [18]). Let $\mathfrak{F}$ be the homogeneous structure from Theorem 1 associated to $\mathcal{R}$.

We say that a set $S \subseteq F$ is correctly labeled if, for every $k$-ary $R \in \tau^{\prime} \cup \sigma^{\prime}$ and every $k$-ary tuple $\bar{t}$ over $S$, we have $\mathfrak{F} \models R^{+}(\bar{t}) \Leftrightarrow \neg R^{-}(\bar{t})$. Now consider the $\{<\} \cup \tau \cup \sigma \cup \rho$-expansion $\overline{\mathfrak{F}}$ of $\mathfrak{F}$ where each $k$-ary $R \in \tau \cup \sigma$ interprets as the $k$-ary relation defined by the quantifierfree first-order formula $R^{+}\left(x_{1}, \ldots, x_{k}\right) \wedge\left\{x_{1}, \ldots, x_{k}\right\}$ is correctly labeled. Since first-order definable relations are preserved by automorphisms, $\overline{\mathfrak{F}}$ is still homogeneous. We define $\mathfrak{B}$ as the $\tau$-reduct of $\overline{\mathfrak{F}}$.
$" \Rightarrow$ " Suppose that $\mathfrak{A} \in \operatorname{CSP}(\mathfrak{B})$, i.e., there exists a homomorphism $h: \mathfrak{A} \rightarrow \mathfrak{B}$. We define $\overline{\mathfrak{A}}$ as the expansion of $\mathfrak{A}$ obtained by pulling back the relations from $\overline{\mathfrak{F}}$ through $h$. Clearly $h$ is a homomorphism from $\overline{\mathfrak{A}}$ to $\overline{\mathfrak{F}}$. Let $\neg \psi_{1} \vee \cdots \vee \neg \psi_{k} \vee \psi_{k+1} \vee \cdots \vee \psi_{\ell}$ be a clause in $\Phi$, where each $\psi_{i}$ is a positive atomic formula. Suppose that $\overline{\mathfrak{A}} \models \psi_{1} \wedge \cdots \wedge \psi_{k}(\bar{a})$. Since $h$ is a homomorphism, we have $\overline{\mathfrak{F}} \models \psi_{1} \wedge \cdots \wedge \psi_{k}(e(\bar{a}))$. For every atom $\psi$ of the form $R(\bar{x})$ for $R \in \tau^{\prime} \cup \sigma^{\prime}$, we define $\psi^{+}$as $R^{+}(\bar{x})$ and $\psi^{-}$as $R^{-}(\bar{x})$. By the definition of $\mathfrak{B}$, we have $\overline{\mathfrak{F}} \models \psi_{1}^{+} \wedge \cdots \wedge \psi_{k}^{+}(e(\bar{a}))$. By the definition of $\overline{\mathfrak{F}}$, we have $\overline{\mathfrak{F}} \models \neg \psi_{k+1}^{-} \vee \cdots \vee \neg \psi_{\ell}^{-}(e(\bar{a}))$, i.e., there exists $i \in[\ell] \backslash[k]$ such that $\overline{\mathfrak{F}} \models \neg \psi_{i}^{-}(e(\bar{a}))$. Since $\Phi$ is guarded, there exists $j \in[k]$ such that all variables $\bar{x}_{i}$ of $\psi_{i}$ are among the variables $\bar{x}_{j}$ of $\psi_{j}$. By the assumption that the the set $\left\{h\left(\bar{x}_{j}\right)[1], \ldots\right\}$ is correctly labeled, we have $\overline{\mathfrak{F}} \models \psi_{i}^{+}(e(\bar{a}))$. Clearly $\left\{h\left(\bar{x}_{i}\right)[1], \ldots\right\}$ is also correctly labeled, and hence $\overline{\mathfrak{F}} \models \psi_{i}(e(\bar{a}))$. Since $\Phi$ is monotone, $\psi_{i}$ is of the form $R(\bar{x})$ for $R \in \sigma^{\prime}$. Hence, by the definition of $\overline{\mathfrak{A}}$, we have $\overline{\mathfrak{A}} \models \psi_{i}(e(\bar{a}))$.
" $\Leftarrow$ " Suppose that $\mathfrak{A} \models \Phi$, and let $\mathfrak{A}_{\Phi}$ be a $\tau \cup \sigma$-expansion of $\mathfrak{A}$ witnessing this fact. We define $\mathfrak{A}^{\prime}$ as the $\tau^{\prime} \cup \sigma^{\prime}$ structure with domain $A$ and where $R^{+}$interprets as $R^{\mathfrak{A}_{\Phi}}$ and $R^{-}$ as the complement of $R^{\mathfrak{A}_{\Phi}}$ in $\mathfrak{A}_{\Phi}$. Then clearly $\mathfrak{A}^{\prime} \models \forall \bar{x}$. $\phi^{\prime}$. Consequently, $\mathfrak{A}^{\prime}$ is a reduct of a substructure $\overline{\mathfrak{A}}$ of $\overline{\mathfrak{F}}$. Clearly, the $\tau$-reduct of $\overline{\mathfrak{A}}$ is isomorphic to $\mathfrak{A}$. It follows that $\mathfrak{A} \in \operatorname{age}(\mathfrak{B})$.

Proof of Lemma 14. " $(2) \Rightarrow(3)$ " This direction is trivial.
$"(4) \Rightarrow(5)$ " This direction is also trivial.
" $(6) \vee(8) \Rightarrow(7)$ " This direction is well-known and easy to see [32].
" $(3) \Rightarrow(6)$ " Since $\Phi_{\mathscr{G}}$ is connected, $\operatorname{fm}\left(\Phi_{\mathscr{G}}\right)$ is preserved by disjoint unions. Since $\Phi_{\mathscr{G}}$ is equivalent to a GMSNP sentence, by the first part of Theorem $23, \Phi_{G}$ is equivalent to a disjunction $\Phi_{1} \vee \cdots \vee \Phi_{k}$ of connected GMSNP sentences. We may assume that $k$ is minimal with this property. If $k \geq 2$, then, by the minimality of $k$, there exist $\mathfrak{A}_{1}, \mathfrak{A}_{2} \in \Phi_{\mathscr{g}}$ such that $\mathfrak{A}_{i} \models \Phi_{i} \wedge \bigwedge_{j \in[k] \backslash\{i\}} \neg \Phi_{j}$ for $i \in\{1,2\}$. But then the disjoint union of $\mathfrak{A}_{1}$ and $\mathfrak{A}_{2}$ does not satisfy $\Phi_{\mathscr{G}}$, a contradiction. Hence, $k=1$. Now the statement follows from the second part of Theorem 23 .
" $(1) \Rightarrow(2) \wedge(4) \wedge(8) "$ By Theorem 20, there exists a DFA $\mathscr{A}$ such that $L(\mathscr{G})=L(\mathscr{A})$. By Lemma 13 and Lemma 22, we have $\mathrm{fm}\left(\Phi_{\mathscr{G}}\right)=\mathrm{fm}\left(\Phi_{\mathscr{A}}\right)$. This implies item (2) because $\Phi_{\mathscr{A}}$ is in connected monadic Datalog. In fact, the sentence falls into an even stricter fragment which was called caterpillar Datalog in [30]. By Theorem 4.1 in [30], there exists a finite structure whose CSP equals $\mathrm{fm}\left(\Phi_{\mathscr{A}}\right)$. This implies item (4). Finally, we show that $\mathrm{fm}\left(\Phi_{\mathscr{G}}\right)$ is finitely bounded homogenizable. Since the universal sentence $\bar{\Phi}_{\mathscr{A}}$ is complete, the class $\mathrm{fm}\left(\bar{\Phi}_{\mathscr{A}}\right)$ is closed under unions, and therefore has the AP. Let $\mathfrak{H}$ be the homogeneous structure from Theorem 1 associated with $\operatorname{fm}\left(\bar{\Phi}_{\mathscr{A}}\right)$. By the definition of $\mathrm{fm}\left(\bar{\Phi}_{\mathscr{A}}\right)$, the signature $\tau_{Q}$ only contains unary symbols $R_{q}$ for those $q \in Q$ which are reachable from $q_{0}$. Let $Q_{0} \subseteq Q$ be the set of states reachable from $q_{0}$ and, for every $q \in Q_{0}$, let $w_{q} \in \Sigma^{+}$be an arbitrary word witnessing that $q$ is reachable from $q_{0}$. Note that, if $q_{1}, q_{2} \in Q_{0}$ are distinct, then $w_{q_{1}} \neq w_{q_{2}}$. For every $w \in \Sigma^{+}$, consider the unary formula

$$
\phi_{w}^{I}\left(x_{1}\right):=\exists x_{2}, \ldots, x_{|w|+1}\left(I\left(x_{|w|+1}\right) \wedge \phi_{w}\left(x_{|w|+1}, \ldots, x_{1}\right)\right) .
$$

We show that, for every $q \in Q_{0}$, the unary formulas $R_{q}(x)$ and $\phi_{w_{q}}^{I}(x)$ define the same relation in $\mathfrak{H}$. Then, for every $q \in Q_{0}$, the relation $R_{q}^{\mathfrak{H}}$ is first-order definable in the $\tau_{\Sigma^{-}}$ reduct of $\mathfrak{H}$ and is therefore preserved by all of its automorphisms. This implies item (8). First, suppose that $\mathfrak{H} \models \phi_{w_{q}}^{I}(x)$ for some $x \in H$. Since $w_{q}$ witnesses that $q$ is reachable from $q_{0}$ and $\mathfrak{H} \models \bar{\Phi}_{\mathscr{I}}$, it follows that $\mathfrak{H} \models R_{q}(x)$. Next, suppose that $\mathfrak{H} \models R_{q}(x)$ for some $x \in H$. Since $\mathscr{A}$ is deterministic, by the definition of $\bar{\Phi}_{\mathscr{A}}$, there exists a structure $\mathfrak{A}$ in the signature of $\mathfrak{H}$ with domain $\left\{x_{\left|w_{q}\right|+1}, \ldots, x_{1}\right\}$ that satisfies $\mathfrak{A} \models \bar{\Phi}_{\mathscr{A}} \wedge I\left(x_{\left|w_{q}\right|+1}\right) \wedge \phi_{w_{q}}\left(x_{\left|w_{q}\right|+1}, \ldots, x_{1}\right)$ and whose substructure on $\left\{x_{1}\right\}$ is isomorphic to the substructure of $\mathfrak{H}$ on $\{x\}$. Since $\mathfrak{A} \models \bar{\Phi}_{\mathscr{l}}$, there exists an embedding $e: \mathfrak{A} \hookrightarrow \mathfrak{H}$. Since $\mathfrak{H}$ is homogeneous, there exists an automorphism $f$ of $\mathfrak{H}$ such that $f \circ e\left(x_{1}\right)=x$. Since automorphisms preserve first-order definable relations, it follows that $\mathfrak{H} \models \phi_{w_{q}}^{I}(x)$.
$"(5) \vee(7) \Rightarrow(1) "$ Let $\mathfrak{D}$ be an $\omega$-categorical structure such that $\mathrm{fm}\left(\Phi_{\mathscr{G}}\right)=$ age $(\mathfrak{D})$ or $\operatorname{fm}\left(\Phi_{\mathscr{G}}\right)=\operatorname{CSP}(\mathfrak{D})$. Suppose, on the contrary, that $L(\mathscr{G})$ is not regular. For every $w \in \Sigma^{+}$, consider the unary formula

$$
\phi_{w}^{T}\left(x_{1}\right):=\exists x_{2}, \ldots, x_{|w|+1}\left(\phi_{w}\left(x_{1}, \ldots, x_{|w|+1}\right) \wedge T\left(x_{|w|+1}\right)\right) .
$$

Since $L(\mathscr{G})$ is not regular, by Theorem $20, \sim_{L(\mathscr{G})}$ has infinitely many classes. Let $w_{1}, \ldots$ be the representatives of the classes. For every $i \geq 1$ let $R_{i} \subseteq D$ be the unary relation defined by $\phi_{w_{i}}^{I}\left(x_{1}\right)$ in $\mathfrak{D}$. For every $i \geq 1$, the formula $\phi_{w_{i}}^{I}\left(x_{1}\right)$ is satisfiable in $\mathfrak{D}$ because it does not contain any $T$-atom. Since first-order formulas are preserved under automorphisms, for every $i \geq 1, R_{i}$ is a non-empty union of unary orbits. By the definition of $\sim_{L(\mathscr{G})}$, for every pair $i \neq j$, there exists $w \in \Sigma^{*}$ such that $\left|\left\{w_{i} w, w_{j} w\right\} \cap L(\mathscr{G})\right|=1$. By Lemma 13 , exactly one of the relations $R_{i}$ and $R_{j}$ contains an element satisfying $\phi_{w}^{T}\left(x_{1}\right)$ in $\mathfrak{D}$. In other words, there exists an orbit that is contained in one of the two relations but not in the other. This can only be the case for all $i \neq j$ if there are infinitely many unary orbits, a contradiction to $\omega$-categoricity. Therefore, $L(\mathscr{G})$ is regular.

## B Proofs of Theorem 5 and Theorem 6

In the next two subsections, we only provide the exact specifications of the conjuncts in $\Phi_{1}$ and $\Phi_{2}$. The actual proof of the theorems remains almost unchanged, except for the small detail that the structures $\mathfrak{B}_{1}, \mathfrak{B}_{2}$ from the first part must additionally satisfy the formula $N(\mathbf{0}, 1)$. The presence of this atom will be explained later, but we can already reveal that it has to do with the simple mechanism for distinguishing between the variables 0 and 1 .

## B. 1 Inputs specified by universal sentences

The first part $\Phi_{1}$ does not explain how our reduction works, but ensures that it does not fall apart, e.g., due to ill-behaved identifications of variables. For every $\alpha \in T$, the signature $\tau$ contains an $(n+1)$-ary symbol $T_{\alpha}$. The first $n$ arguments in a $T_{\alpha}$-atom serve as binary counters, and the last argument carries a given path node $p$. Suppose that the variables o and 1 represent the bits 0 and 1 , respectively. Then each atomic formula $T_{\alpha}\left(c_{1}, \ldots, c_{n}, p\right)$ with $c_{1}, \ldots, c_{n} \in\{0,1\}$ represents the situation in which a tile $\alpha$ is present in the $p$-th row and in the $\left(1+\sum_{k \in[n]}\left(c_{k}=1\right) \cdot 2^{n-k}\right)$-th column. First, we want to ensure the horizontal consistency of the tiling. To this end, for every pair $(\alpha, \beta) \in T^{2} \backslash P_{h}^{\mathfrak{T}}$, we include in $\Phi_{1}$ a complete Horn sentence ensuring that two horizontally adjacent positions in the $p$-th row cannot be tiled with $\alpha$ and $\beta$. Here, we encode the successor relation w.r.t. binary addition using a combination of equalities: $\left(c_{n+1}, \ldots, c_{2 n}\right)$ is the successor of $\left(c_{1}, \ldots, c_{n}\right)$ if and only if there exists $j \in[n]$ such that

- $c_{i}=c_{i+n} \in\{0,1\}$ for every $i \in[j-1]$,
- $c_{j}=\mathrm{O}$ and $c_{n+j}=1$, and
- $c_{i}=1$ and $c_{i+n}=0$ for every $i \in[n] \backslash[j]$.

This encoding only makes sense if 0 and 1 truly represent the bits 0 and 1 , so we introduce a simple mechanism (in terms of a Horn sentence) that distinguishes between the variables o and 1. We include in $\tau$ the binary symbol $N$ that will later be used to distinguish between 0 and 1 , and the following sentences as conjuncts in $\Phi_{1}$ :

$$
\begin{equation*}
\forall x, y(N(x, y) \wedge N(y, x) \Rightarrow \perp) \tag{19}
\end{equation*}
$$

and, for every pair $(\alpha, \beta) \in T^{2} \backslash P_{h}^{\mathcal{T}}$, the sentence

$$
\left.\begin{array}{l}
\forall p, \mathrm{o}, 1, c_{1}, \ldots, c_{2 n} \\
\left(\begin{array}{c}
N(\mathrm{o}, 1) \wedge T_{\alpha}\left(c_{1}, \ldots, c_{n}, p\right) \wedge T_{\beta}\left(c_{n+1}, \ldots, c_{2 n}, p\right) \\
\wedge\left(\bigvee_{j \in[n]} \bigwedge_{i \in[j-1]}\left(c_{i}=\mathrm{O} \wedge c_{i+n}=\mathrm{o} \vee c_{i}=1 \wedge c_{i+n}=1\right)\right. \\
\left.\wedge c_{j}=\mathrm{o} \wedge c_{j+n}=1 \wedge \bigwedge_{i \in[n] \backslash[j]} c_{i}=1 \wedge c_{i+n}=\mathrm{o}\right)
\end{array}\right. \\
\Downarrow \\
\perp
\end{array}\right) . .
$$

Next, we want to ensure that every position in the $p$-th row is occupied by at most one tile. To this end, for every $(\alpha, \beta) \in T^{2}$ with $\alpha \neq \beta$, we include

$$
\forall p, \mathrm{o}, 1, c_{1}, \ldots, c_{n}\left(T_{\alpha}\left(c_{1}, \ldots, c_{n}, p\right) \wedge T_{\beta}\left(c_{1}, \ldots, c_{n}, p\right) \wedge \bigwedge_{i \in[n]}\left(c_{i}=\mathrm{o} \vee c_{i}=1\right) \Rightarrow \perp\right)
$$

as a conjunct in $\Phi_{1}$. Finally, we want to ensure that each verifier node $v$ represents at most one number from $\left[2^{n}\right]$. For every $i \in[n], \tau$ contains two unary symbols $0_{i}$ and $1_{i}$ which
will be used to encode numbers in binary. We include $\forall v\left(\bigvee_{i \in[n]} \mathrm{O}_{i}(v) \wedge 1_{i}(v) \Rightarrow \perp\right)$ as the last conjunct in $\Phi_{1}$. Now the idea is that the combinations of atomic formulas $\mathrm{O}_{i}(v)$ and $1_{i}(v)$ at a verifier node $v$ will be compared with the combinations of 0 and 1 in atomic formulas $T_{\alpha}\left(c_{1}, \ldots, c_{n}, p\right)$. The Horn sentences in the second part of $\Phi$ will be formulated so that verifying the presence of all $2^{n}$ atoms of the form $T_{\alpha}\left(c_{1}, \ldots, c_{n}, p_{1}\right)$ at a path node $p_{1}$ using verifier nodes is the only possible way to progress to a next path node $p_{2}$. As a consequence, we do not need to add an explicit requirement for rows, represented by path nodes, to be completely tiled from left to right. For the same reason, we also do not need to add an explicit requirement for verifier nodes to represent at least one number from [ $2^{n}$ ].

We now proceed with the sentence $\Phi_{2}$, which explains how the parsing of a tiling actually works. We use $\operatorname{SUCC}\left(v_{1}, v_{2}\right)$ as a shortcut for the formula

$$
\left.\left.\begin{array}{rl}
\bigvee_{j \in[n]} & \bigwedge_{i \in[j-1]}\left(\mathrm{O}_{i}\left(v_{1}\right)\right.
\end{array}\right) \mathrm{O}_{i}\left(v_{2}\right) \vee 1_{i}\left(v_{1}\right) \wedge 1_{i}\left(v_{2}\right)\right) .
$$

We will need $\operatorname{SUCC}\left(v_{1}, v_{2}\right)$ to represent the successor relation for verifier nodes. We will also need an auxiliary formula for testing whether a sequence of bits represents the same number as a particular verifier node. This is achieved using the formula $\mathrm{EQ}\left(v, \mathbf{o}, 1, c_{1}, \ldots, c_{n}\right)$, which is defined as

$$
\bigwedge_{j \in[n]}\left(\mathrm{O}_{j}(v) \wedge c_{j}=\mathrm{o} \vee 1_{j}(v) \wedge c_{j}=1\right)
$$

Finally, we use $\operatorname{PAD}\left(y_{1}, y_{2}, x_{1}, \ldots, x_{k}\right)$ as a shortcut for the formula

$$
L\left(y_{1}\right) \wedge R\left(y_{2}\right) \wedge \bigwedge_{i \in[k]} E\left(y_{1}, x_{i}\right) \wedge E\left(y_{2}, x_{i}\right) \wedge \bigwedge_{j \in[k]} E\left(x_{i}, x_{j}\right)
$$

The parsing of a tiling starts from a path node $p$ representing a row whose leftmost position contains a tile that can be present in the bottom left corner of a tiling grid. This must be confirmed by a verifier node, in which case a 6 -ary $Q_{b}$-atom is derived, representing the fact that the leftmost column of the $p$-th row has been checked. To this end, we include in $\Phi_{2}$ suitable Horn sentences for every $\alpha \in P_{\ell}^{\mathfrak{T}} \cap P_{b}^{\mathfrak{T}}$ :

$$
\begin{align*}
& \forall y_{1}, y_{2}, p, v, \mathrm{O}, 1, c_{1}, \ldots, c_{n} \\
& \left(\begin{array}{c}
\begin{array}{c}
N(\mathrm{O}, 1) \wedge T_{\alpha}\left(c_{1}, \ldots, c_{n}, p\right) \wedge \bigwedge_{j \in[n]} c_{j}=\mathrm{O} \\
\wedge \mathrm{EQ}\left(v, \mathrm{O}, 1, c_{1}, \ldots, c_{n}\right) \wedge \operatorname{PAD}\left(y_{1}, y_{2}, p, z, \mathrm{O}, 1\right)
\end{array}
\end{array}\right) \tag{20}
\end{align*}
$$

Note that, by (19), the presence of the atom $N(\mathbf{O}, \mathbf{1})$ in (20) creates an asymmetry between 0 and 1. At this point, it might not be clear in which sense 0 and 1 represent 0 and 1 , respectively, and not the other way around. However, a detailed inspection of the construction reveals that this will be achieved implicitly through the use of EQ and SUCC. These sentences form the only non-complete part of $\Phi$; we intentionally leave a missing edge between $y_{1}$ and $y_{2}$ in the Gaifman graph to enable potential formation of AP failures.

Using $2^{n}$-many verifier nodes and propagation of $Q_{b}$-atoms, the whole bottom row is checked for the presence of tiles. Their horizontal consistency already follows from the conditions imposed on path nodes by $\Phi_{2}$ and needs not to be checked during this step. To
this end, we include in $\Phi_{2}$ suitable Horn sentences for every $\alpha \in P_{b}^{\mathfrak{T}}$ :

$$
\left.\begin{array}{l}
\forall y_{1}, y_{2}, p, v_{1}, v_{2}, \mathrm{o}, 1, c_{1}, \ldots, c_{n} \\
\left(\begin{array}{c}
\Downarrow \\
\underbrace{}_{\alpha}\left(c_{1}, \ldots, c_{n}, p\right) \wedge \operatorname{EQ}\left(v_{1}, \mathrm{o}, 1, c_{1}, \ldots, c_{n}\right) \wedge \operatorname{SUCC}\left(v_{1}, v_{2}\right) \\
\wedge Q_{b}\left(y_{1}, y_{2}, p, v_{1}, \mathrm{o}, 1\right) \wedge \operatorname{PAD}\left(y_{1}, y_{2}, p, v_{1}, v_{2}, \mathrm{o}, \mathbf{1}\right)
\end{array}\right.
\end{array}\right) . .
$$

After the $p$-th row has been checked by a $2^{n}$-th verifier node, we mark the variable $p$ with a $Q$-atom that indicates that the parsing can progress to a successor path node. To this end, we include in $\Phi_{2}$ suitable Horn sentences for every $\alpha \in P_{b}^{\mathfrak{T}} \cap P_{r}^{\mathfrak{T}}$ :

$$
\left.\begin{array}{l}
\forall y_{1}, y_{2}, p, v, \mathbf{o}, 1, c_{1}, \ldots, c_{n} \\
\left(\begin{array}{c}
\Downarrow \\
\underbrace{}_{\alpha}\left(c_{1}, \ldots, c_{n}, p\right) \wedge \bigwedge_{j \in[n]} c_{j}=1 \wedge \operatorname{EQ}\left(v, \mathbf{o}, 1, c_{1}, \ldots, c_{n}\right) \\
\wedge Q_{b}\left(y_{1}, y_{2}, p, v, \mathbf{o}, 1\right) \wedge \operatorname{PAD}\left(y_{1}, y_{2}, p, v, \mathbf{o}, 1\right)
\end{array}\right.
\end{array}\right) . .
$$

The successor relation for path nodes is represented by the binary symbol $S$, and the certificate of vertical verification for pairs $\left(p_{1}, p_{2}\right)$ of successive path nodes is represented by the 7-ary symbol $Q_{v}$. For every $(\alpha, \beta) \in P_{v}^{\mathfrak{T}} \cap\left(P_{\ell}^{\mathfrak{T}}\right)^{2}$, we include in $\Phi_{2}$ a Horn sentence verifying the vertical consistency of the leftmost positions in the rows $p_{1}$ and $p_{2}$ and deriving the first $Q_{v}$-atom containing $p_{1}$ and $p_{2}$, but only if there is a $Q$-atom containing $p_{1}$ :

$$
\begin{aligned}
& \forall y_{1}, y_{2}, p_{1}, p_{2}, v, \mathrm{o}, 1, c_{1}, \ldots, c_{2 n} \\
& \binom{\begin{array}{c}
S\left(p_{1}, p_{2}\right) \wedge \operatorname{EQ}\left(v, \mathrm{o}, 1, c_{1}, \ldots, c_{n}\right) \wedge \bigwedge_{j \in[n]} c_{j}=\mathrm{o} \wedge \operatorname{EQ}\left(v, \mathrm{o}, 1, c_{n+1}, \ldots, c_{2 n}\right) \\
\wedge \wedge j \in[n]^{c_{j+n}=\mathrm{o} \wedge T_{\alpha}\left(c_{1}, \ldots, c_{n}, p_{1}\right) \wedge T_{\beta}\left(c_{n+1}, \ldots, c_{2 n}, p_{2}\right)} \\
\wedge Q\left(y_{1}, y_{2}, p_{1}, \mathrm{o}, 1\right) \wedge \operatorname{PAD}\left(y_{1}, y_{2}, p_{1}, p_{2}, v, \mathrm{o}, 1\right)
\end{array}}{\Downarrow}
\end{aligned}
$$

Next, for every $(\alpha, \beta) \in P_{v}^{\mathcal{T}}$, we include in $\Phi_{2}$ a Horn sentence verifying the vertical consistency for the intermediate positions by deriving further $Q_{v}$-atoms containing $p_{1}$ and $p_{2}$ :

$$
\left.\begin{array}{l}
\forall y_{1}, y_{2}, p_{1}, p_{2}, v_{1}, v_{2}, \mathrm{o}, 1, c_{1}, \ldots, c_{2 n} \\
\left(\begin{array}{c}
\begin{array}{c}
\operatorname{SUCC}\left(v_{1}, v_{2}\right) \wedge \operatorname{EQ}\left(v_{1}, \mathrm{o}, 1, c_{1}, \ldots, c_{n}\right) \wedge \operatorname{EQ}\left(v_{1}, \mathrm{o}, 1, c_{n+1}, \ldots, c_{2 n}\right) \\
\wedge T_{\alpha}\left(c_{1}, \ldots, c_{n}, p_{1}\right) \wedge T_{\beta}\left(c_{n+1}, \ldots, c_{2 n}, p_{2}\right) \wedge Q_{v}\left(y_{1}, y_{2}, p_{1}, p_{2}, v_{1}, \mathrm{o}, 1\right) \\
\wedge \operatorname{PAD}\left(y_{1}, y_{2}, p_{1}, p_{2}, v_{1}, v_{2}, \mathrm{o}, 1\right)
\end{array} \\
Q_{v}\left(y_{1}, y_{2}, p_{1}, p_{2}, v_{2}, \mathrm{o}, 1\right)
\end{array}\right.
\end{array}\right) .
$$

And finally, for every $(\alpha, \beta) \in P_{v}^{\mathfrak{T}} \cap\left(P_{r}^{\mathfrak{T}}\right)^{2}$, we include in $\Phi_{2}$ a Horn sentence verifying the vertical consistency of the leftmost positions in the rows $p_{1}$ and $p_{2}$ and deriving the first
$Q$-atom containing $p_{2}$ only:
$\forall y_{1}, y_{2}, p_{1}, p_{2}, v, \mathbf{o}, 1, c_{1}, \ldots, c_{2 n}$

$$
\left(\begin{array}{c}
\begin{array}{c}
\operatorname{EQ}\left(v, \mathbf{o}, 1, c_{1}, \ldots, c_{n}\right) \wedge \bigwedge_{j \in[n]} c_{j}=1 \wedge \operatorname{EQ}\left(v, \mathbf{o}, 1, c_{n+1}, \ldots, c_{2 n}\right) \\
\wedge \bigwedge_{j \in[n]} c_{j+n}=1 \wedge T_{\alpha}\left(c_{1}, \ldots, c_{n}, p_{1}\right) \wedge T_{\beta}\left(c_{n+1}, \ldots, c_{2 n}, p_{2}\right) \\
\wedge Q_{v}\left(y_{1}, y_{2}, p_{1}, p_{2}, v, \mathbf{o}, 1\right) \wedge \operatorname{PAD}\left(y_{1}, y_{2}, p_{1}, p_{2}, v, \mathbf{o}, 1\right)
\end{array} \\
\Downarrow \\
Q\left(y_{1}, y_{2}, p_{2}, \mathbf{o}, \mathbf{1}\right)
\end{array}\right)
$$

The top row is verified using a 6 -ary symbol $Q_{t}$ similarly as the bottom row; however, the verification of the rightmost position in the top row results in the derivation of $\perp$. We include the following sentences as conjuncts in $\Phi_{2}$ : for every $\alpha \in P_{\ell}^{\mathfrak{T}} \cap P_{t}^{\mathfrak{T}}$, the sentence

$$
\begin{aligned}
& \forall y_{1}, y_{2}, p, v, \mathbf{o}, 1, c_{1}, \ldots, c_{n} \\
& \binom{\underbrace{\operatorname{EQ}\left(v, \mathbf{o}, 1, c_{1}, \ldots, c_{n}\right) \wedge \wedge_{j \in[n]} c_{j}=\mathrm{o} \wedge T_{\alpha}\left(c_{1}, \ldots, c_{n}, p\right)}_{\Downarrow}}{\wedge Q\left(y_{1}, y_{2}, p, \mathbf{0}, 1\right) \wedge \operatorname{PAD}\left(y_{1}, y_{2}, p, v, \mathbf{o}, 1\right)},
\end{aligned}
$$

for every $\alpha \in P_{t}^{\mathfrak{T}}$, the sentence

$$
\left.\begin{array}{l}
\forall y_{1}, y_{2}, p, v_{1}, v_{2}, \mathrm{o}, 1, c_{1}, \ldots, c_{n} \\
\binom{\operatorname{SUCC}\left(v_{1}, v_{2}\right) \wedge \operatorname{EQ}\left(v_{1}, \mathrm{o}, 1, c_{1}, \ldots, c_{n}\right) \wedge T_{\alpha}\left(c_{1}, \ldots, c_{n}, p\right)}{\underbrace{\wedge Q_{t}\left(y_{1}, y_{2}, p, v_{1}, \mathrm{o}, 1\right) \wedge Q\left(y_{1}, y_{2}, p, \mathrm{o}, 1\right) \wedge \operatorname{PAD}\left(y_{1}, y_{2}, p, v_{1}, v_{2}, \mathrm{o}, 1\right)}_{\Downarrow}}
\end{array}\right) .
$$

and, for every $\alpha \in P_{t}^{\mathfrak{T}} \cap P_{r}^{\mathfrak{T}}$, the sentence

$$
\left.\begin{array}{l}
\forall y_{1}, y_{2}, p, v, \mathrm{o}, 1, c_{1}, \ldots, c_{n} \\
\left(\begin{array}{c}
\operatorname{EQ}\left(v, \mathrm{o}, 1, c_{1}, \ldots, c_{n}\right) \wedge \bigwedge_{j \in[n]} c_{j}=1 \wedge T_{\alpha}\left(c_{1}, \ldots, c_{n}, p\right) \\
\underbrace{\wedge Q_{t}\left(y_{1}, y_{2}, p, v, \mathrm{o}, 1\right) \wedge Q\left(y_{1}, y_{2}, p, \mathrm{o}, 1\right) \wedge \operatorname{PAD}\left(y_{1}, y_{2}, p, v, \mathrm{o}, 1\right)}_{\Downarrow} \\
\perp
\end{array}\right. \tag{21}
\end{array}\right) . .
$$

## B. 2 Inputs specified by sets of bounds

We include in $\tau$ a symbol $I$ of arity $\left\lceil\log _{2}|T| \cdot n\right\rceil+1$. The first $\left\lceil\log _{2}|T| \cdot n\right\rceil$ entries serve as binary counters to represent the pairs $(i, \alpha) \in[n] \times T$ in binary, and the last entry carries a path node representing a row of the tiling grid. Each pair $(i, \alpha) \in[n] \times T$ is to be interpreted as the fact that the $i$-th column in the row represented by a particular path node contains the tile $\alpha$. The reason for this choice of encoding is that we aim to construct a universal sentence $\Phi$ which is equivalent to a set of forbidden substructures $\mathcal{N}$ of size polynomial in $|T| \cdot n$. To achieve this, we use a constant number of symbols whose arity is logarithmic in the size of the input.

Suppose that 0 and 1 are two variables representing the bits 0 and 1 , respectively. For each pair $(i, \alpha) \in[n] \times T$, the ternary formula $\operatorname{TILE}_{i, \alpha}(\mathbf{0}, 1, p)$ is the $I$-atom whose last entry contains the variable $p$ and the first $\left\lceil\log _{2}|T| \cdot n\right\rceil$ entries contain the variables 0 and 1 in the unique way that represents the number $i \cdot \alpha$ in binary when read from left to right. Note that the number of such formulas is polynomial in the size of the input to the tiling problem. In contrast to the proof of Theorem 5, it is not necessary to introduce any verifier nodes as the number of columns in the tiling grid is polynomial in the size of the input. The sentence $\Phi:=\Phi_{1} \wedge \Phi_{2}$ is defined similarly as in the proof of Theorem 5 , so we only provide a general overview and highlight the main differences.

We start with $\Phi_{1}$. As before, we include the following sentence as a disjunct in $\Phi_{1}$ :

$$
\forall x, y(N(x, y) \wedge N(y, x) \Rightarrow \perp) .
$$

We want each row to be horizontally consistent. For all $i \in[n-1]$ and $(\alpha, \beta) \in T^{2} \backslash P_{h}^{\mathfrak{T}}$, we include the following sentence as a conjunct in $\Phi_{1}$ :

$$
\forall p, \mathbf{o}, \mathbf{1}\left(N(\mathbf{o}, \mathbf{1}) \wedge \operatorname{TILE}_{i, \alpha}(\mathbf{o}, \mathbf{1}, p) \wedge \operatorname{TILE}_{i+1, \beta}(\mathbf{o}, \mathbf{1}, p) \Rightarrow \perp\right)
$$

We also want each position in a given row to be occupied by at most one tile. For all $i \in[n], \alpha, \beta \in T$, we include the following sentence as a conjunct in $\Phi_{1}$ :

$$
\forall p, \mathbf{o}, 1\left(\operatorname{TILE}_{i, \alpha}(\mathbf{o}, 1, p) \wedge \operatorname{TILE}_{i, \beta}(\mathbf{o}, 1, p) \Rightarrow \perp\right)
$$

As in the proof of Theorem 6, we do not need to include an explicit condition stating that each row must be completely tiled from left to right.

We continue with $\Phi_{2}$. For the purpose of verifying the validity of a tiling, we include in $\tau$ a 5 -ary symbol $Q$, a $\left(\left\lceil\log _{2}|T| \cdot n\right\rceil+4\right)$-ary symbol $Q_{v}$, and two $\left(\left\lceil\log _{2}|T| \cdot n\right\rceil+3\right)$-ary symbols $Q_{b}, Q_{t}$. For each pair $(i, \alpha) \in[n] \times T$, the formulas

$$
\operatorname{BOT}_{i, \alpha}\left(\mathbf{0}, \mathbf{1}, p, y_{1}, y_{2}\right), \quad \operatorname{TOP}_{i, \alpha}\left(\mathbf{0}, 1, p, y_{1}, y_{2}\right), \quad \text { and } \quad \operatorname{VERT}_{i, \alpha}\left(\mathbf{0}, 1, p_{1}, p_{2}, y_{1}, y_{2}\right)
$$

are defined analogously to $\operatorname{TILE}_{i, \alpha}(\mathbf{0}, \mathbf{1}, p)$ but using the $Q_{b}, Q_{t}$ and $Q_{v}$-atoms instead. We use them to verify the bottom row, top row, and the vertical consistency of a given tiling. In contrast to $\operatorname{TILE}_{i, \alpha}$, the parameter $\alpha$ is not important in $\mathrm{BOT}_{i, \alpha}, \mathrm{TOP}_{i, \alpha}$, and $\mathrm{VERT}_{i, \alpha}$. The formula $\operatorname{PAD}\left(y_{1}, y_{2}, x_{1}, \ldots, x_{k}\right)$ is defined as in the previous subsection.

The parsing of a tiling starts from a path node $p$ representing a row whose leftmost position contains a tile that can be present in the bottom left corner of a tiling grid. We include the following sentences as conjuncts in $\Phi_{2}$. For all $\alpha \in P_{\ell}^{\mathfrak{T}} \cap P_{b}^{\mathfrak{T}}, \gamma \in T$ :
$\forall y_{1}, y_{2}, p, \mathbf{o}, 1$

$$
\binom{\underbrace{N(\mathrm{o}, 1) \wedge \operatorname{TILE}_{1, \alpha}(\mathrm{o}, 1, p) \wedge \operatorname{PAD}\left(y_{1}, y_{2}, \mathrm{o}, 1, p\right)}_{\Downarrow}}{\operatorname{BOT}_{1, \gamma}\left(\mathrm{o}, 1, p, y_{1}, y_{2}\right)}
$$

for all $i \in[n-1], \alpha, \beta \in P_{b}^{\mathfrak{T}}, \gamma \in T$ :

$$
\begin{aligned}
& \forall y_{1}, y_{2}, p, \mathbf{o}, 1 \\
& \binom{\underbrace{\operatorname{TILE}_{i, \alpha}(\mathbf{o}, \mathbf{1}, p) \wedge \operatorname{TILE}_{i+1, \beta}(\mathbf{o}, \mathbf{1}, p)}_{\Downarrow}}{\wedge \operatorname{BOT}_{i, \gamma}\left(\mathbf{o}, \mathbf{1}, p, y_{1}, y_{2}\right) \wedge \operatorname{PAD}\left(y_{1}, y_{2}, \mathbf{o}, 1, p\right)},
\end{aligned}
$$

and, for all $\alpha \in P_{r}^{\mathfrak{T}} \cap P_{b}^{\mathfrak{T}}, \gamma \in T$ :
$\forall y_{1}, y_{2}, p, \mathbf{o}, 1$

The successor relation for path nodes is represented by the binary symbol $S$. We include the following sentences as conjuncts in $\Phi_{2}$. For all $(\alpha, \beta) \in P_{v}^{\mathfrak{T}} \cap\left(P_{\ell}^{\mathfrak{T}}\right)^{2}, \gamma \in T$ :

$$
\begin{aligned}
& \forall y_{1}, y_{2}, p_{1}, p_{2}, \mathrm{o}, 1 \\
& \binom{\begin{array}{c}
S\left(p_{1}, p_{2}\right) \wedge \operatorname{TILE}_{1, \alpha}\left(\mathrm{o}, 1, p_{1}\right) \wedge \operatorname{TILE}_{1, \beta}\left(\mathrm{o}, 1, p_{2}\right) \\
\wedge Q\left(\mathrm{o}, 1, p_{1}, y_{1}, y_{2}\right) \wedge \operatorname{PAD}\left(y_{1}, y_{2}, \mathrm{o}, 1, p_{1}, p_{2}\right)
\end{array}}{\Downarrow}
\end{aligned}
$$

for every $i \in[n-1],(\alpha, \beta) \in P_{v}^{\mathcal{T}}, \gamma \in T$ :

$$
\begin{aligned}
& \forall y_{1}, y_{2}, p_{1}, p_{2}, \mathbf{o}, 1 \\
& \binom{\operatorname{TILE}_{i, \alpha}\left(\mathbf{o}, 1, p_{1}\right) \wedge \operatorname{TILE}_{i, \beta}\left(\mathbf{o}, 1, p_{2}\right)}{\underbrace{\wedge \operatorname{VERT}_{i, \gamma}\left(\mathbf{o}, 1, p_{1}, p_{2}, y_{1}, y_{2}\right) \wedge \operatorname{PAD}\left(y_{1}, y_{2}, \mathbf{o}, 1, p_{1}, p_{2}\right)}_{\forall}}
\end{aligned}
$$

and, for all $(\alpha, \beta) \in P_{v}^{\mathfrak{T}} \cap\left(P_{r}^{\mathfrak{T}}\right)^{2}, \gamma \in T$ :

The top row is verified in a similar fashion as the bottom row, except that the nullary falsity predicate is derived at the end of the verification process. We include the following sentences as conjuncts in $\Phi_{2}$. For all $\alpha \in P_{\ell}^{\mathfrak{T}} \cap P_{t}^{\mathfrak{T}}, \gamma \in T$ :

$$
\begin{aligned}
& \forall y_{1}, y_{2}, p, \mathbf{o}, 1 \\
& (\underbrace{\operatorname{TILE}_{1, \alpha}(\mathbf{o}, 1, p) \wedge Q\left(\mathbf{o}, 1, p, y_{1}, y_{2}\right) \wedge \operatorname{PAD}\left(y_{1}, y_{2}, \mathbf{o}, 1, p\right)}_{\begin{array}{|c}
\Downarrow \\
\operatorname{TOP}_{1, \gamma}\left(\mathbf{o}, 1, p, y_{1}, y_{2}\right)
\end{array}})
\end{aligned}
$$

for every $i \in[n-1], \alpha, \beta \in P_{t}^{\mathfrak{T}}, \gamma \in T$ :
$\forall y_{1}, y_{2}, p, \mathbf{o}, 1$

$$
\binom{\operatorname{TILE}_{i, \alpha}(\mathbf{o}, \mathbf{1}, p) \wedge \operatorname{TILE}_{i+1, \beta}(\mathbf{o}, \mathbf{1}, p)}{\wedge \operatorname{TOP}_{i, \gamma}\left(\mathbf{o}, 1, p, y_{1}, y_{2}\right) \wedge \operatorname{PAD}\left(y_{1}, y_{2}, \mathbf{o}, 1, p\right)}
$$

and, for all $\alpha \in P_{r}^{\mathfrak{T}} \cap P_{t}^{\mathfrak{T}}, \gamma \in T$ :
$\forall y_{1}, y_{2}, p, \mathbf{o}, 1$

[^0]:    1 The correspondence between MMSNP and finite-domain CSP was initially only achieved up to randomized reductions, but it was later derandomized by Kun [36].

[^1]:    ${ }^{2}$ In [49], this problem is called the corridor tiling problem.

[^2]:    ${ }^{3}$ This observation was first made in [12], see the proof of Theorem 7.
