On the Capacity Region of Reconfigurable Intelligent Surface Assisted Symbiotic Radios

Qianqian Zhang, Hu Zhou, Ying-Chang Liang, *Fellow, IEEE*, Sumei Sun, *Fellow, IEEE*, Wei Zhang, *Fellow, IEEE*, and H. Vincent Poor, *Fellow, IEEE*

Abstract—In this paper, we are interested in a reconfigurable intelligent surface (RIS)-assisted symbiotic radio (SR) system, where an RIS assists a primary transmission by passive beamforming and simultaneously acts as an information transmitter by periodically adjusting its reflection coefficients. The above RIS functions innately enable a new multiplicative multiple access channel (M-MAC), where the primary and secondary signals are superposed in a multiplicative manner. To pursue the fundamental performance limits of M-MAC, we focus on the characterization of the capacity region for such a system when the direct link is blocked. Due to the reflection nature of RIS, the signal transmitted from the RIS should satisfy a passive reflection constraint. We consider two types of passive reflection constraints, one for the case that only the phases of the RIS can be adjusted, while the other for the case that both the amplitude and the phase can be adjusted. Under the passive reflection constraints at the RIS as well as the average power constraint at the primary transmitter (PTx), we characterize the capacity region of RIS-assisted SR. It is observed that: 1) the number of sum-rate-optimal points on the boundary of the capacity region is infinite; 2) for the rate pairs with the maximum sum rate, the optimal distribution of the amplitude of the primary signal is a continuous Rayleigh distribution, while for the remaining rate pairs on the capacity region boundary, the optimal amplitude of the primary signal is discrete; 3) the adjustment of the amplitude for the RIS can enlarge the capacity region as compared to the phase-adjusted-only case.

Index Terms—Symbiotic radio, reconfigurable intelligent surface, capacity region, multiplicative multiple access channel.

I. INTRODUCTION

W IRELESS communication systems continue to strive for ever higher data rates and more access devices. It is envisioned that the sixth generation (6G) mobile networks will accommodate up to 1 terabyte per second (Tb/s) peak data rates and more than 10⁷ connections per square kilometer [2], [3]. This is a particularly challenging task for wireless communication due to the availability of limited power and spectrum resources [4], [5]. Symbiotic radio (SR) has emerged as a promising technology to overcome the challenges of spectrum scarcity and high power consumption due to its spectrum- and power-sharing natures. Specifically, in SR, a passive secondary transmitter (STx) modulates its information over the signal emitted from a primary transmitter (PTx) by periodically adjusting its reflecting coefficient [6]–[8]. This modulation scheme innately enables the STx to transmit information without dedicated spectrum and energy resources, thereby yielding high spectral and energy efficiencies [9]. In return, the secondary transmission provides multipath gain to the primary transmission, thereby yielding mutual benefits between the two transmissions [10]. Due to such mutualistic features and high spectral and energy efficiencies, SR has attracted extensive attention from both academia and industry recently [11], [12].

1

In SR, a number of studies have been carried out on the mutualistic relationship, receiver design, and resource allocation schemes. Particularly, a mutualistic condition of SR through which both primary and secondary transmissions can benefit each other is analyzed in [10] from the perspective of bit error rate (BER) performance. Various types of detectors and their corresponding BERs are studied in [13]. In [14], stochastic optimization techniques are used to design the transceiver for the SR system. In [15] and [16], a constellation learning detector and an iterative detector are designed, respectively, to recover signals transmitted from the STx when the secondary receiver does not have the pilot information of the primary transmission. As for resource allocation schemes, beamforming vectors of the PTx are designed in [17] and [18] under infiniteblock length and finite-block length scenarios, respectively. A transmit power minimization problem is studied in [19] for a multi-user SR system to design the beamforming vectors of multiple PTxs.

To address the double fading effect associated with SR, reconfigurable intelligent surface (RIS) has been proposed to act as the STx for SR. Specifically, in an RIS-assisted SR system, the RIS delivers information by periodically adjusting its reflection coefficients, which is an extension of backscatter modulation [20]. Besides, RIS can also deliver information by spatial modulation [21], [22] and symbol level precoding [22], [23]. Meanwhile, a novel modulation scheme is proposed for the RIS in [24], where the phase-shift matrix of the RIS is divided into two components, one to assist primary transmission and the other to deliver messages. To balance the performance between primary and secondary transmissions, an RIS partitioning scheme is developed in [25], in which the RIS is partitioned into two sub-surfaces to assist primary transmission and to transmit signals, respectively. The effect of the number of reflecting elements of the RIS on mutualistic mechanisms is analyzed in [26]. Moreover, in [27], the capacity of RIS-assisted SR is derived under discrete transmitted constellation points. The degree-of-freedom of RIS-assisted

Part of this work has been presented in IEEE ICC 2023 [1]. Q. Zhang, H. Zhou, and Y.-C. Poor is with the Department of Electrical and Computer Engineering, Princeton University, Princeton, NJ 08544 USA (e-mail: poor@princeton.edu).

SR is characterized in [28] when PTx and RIS transmit multiple data streams. Furthermore, there are some studies on the joint design of the transmit beamforming at the PTx and the reflection coefficients at the RIS. Particularly, for RIS-assisted MIMO SR, the transmit power minimization problem is investigated in [20]. For RIS-assisted MISO SR, BER minimization, transmit power minimization, and secondary transmission rate maximization problems are studied in [29], [30], and [31], respectively.

Despite the above notable advancements, it is still challenging to address the fundamental performance limits of RISassisted SR systems due to the following two reasons. On one hand, the primary and secondary signals in SR are superposed in a multiplicative manner, which forms a new multiplicative multiple access channel (M-MAC) [32]. Although there are extensive studies on additive multiple access channel (MAC) [33] over the last few decades, the results of additive MAC can not be applied to M-MAC directly. On the other hand, the RIS is a passive device whose input should satisfy a passive reflection constraint. That means the peak amplitude of the signal transmitted from the RIS is limited, and thus the widely studied channel capacities under average power constraints are no longer applicable.

As for M-MAC, in [34], the capacity region of a binary M-MAC without noise has been studied. The capacity region of the M-MAC with noise is characterized under average power constraints in [35]. It is worth noting that the capacity region in the above two cases is a triangle. Meanwhile, there are several studies on single-user channel capacity with peak power constraints. In this scenario, the most interesting results are due to Smith [36], which indicate that the capacityachieving distribution is discrete with a finite number of mass points. In [37], a peak power limited quadrature Gaussian channel is considered, in which the optimal input distribution is supported on a finite number of concentric circles, i.e., discrete amplitude and uniform independent phase. The ndimensional vector Gaussian noise channel is investigated under peak power constraints in [38], where the optimal input distribution is geometrically characterized by concentric spheres. Moreover, there are some studies on the characterization of capacity region under peak power constraints over an additive MAC [39], [40], which show that any point on this capacity region boundary can be achieved by discrete input distributions of finite support. Despite of all of this, when M-MAC meets passive reflection constraints, the optimal input distributions and the capacity region of RIS-assisted SR are still unknown.

In this paper, we are interested in the characterization of capacity region for an RIS-assisted SR system. Since the presence or absence of a direct link will lead to different capacity regions, we focus on the blocked direct link case in this paper. We consider two types of passive reflection constraints, one for which only the phases of the RIS can be adjusted, while the other for which both the amplitude and the phase can be adjusted. To pursue the fundamental performance limits of such a system, we first analyze optimal distributions of transmitted signals under average power constraint at the PTx and passive reflection constraint at

the RIS, and then derive the maximum achievable rates for both primary and secondary transmissions as well as their maximum sum rate. Then, we derive the optimal distributions of transmitted signals for the rate pairs on the boundary of the capacity region and characterize the capacity region of RIS-assisted SR with the two types of passive reflection constraints. The main theoretical results are summarized as follows: 1) the secondary transmission achieves the maximum rate when the PTx transmits a sinusoidal signal with the blocked direct link; 2) when the amplitude of the RIS can be adjusted, the capacity-achieving distribution of the secondary signal is geometrically characterized by concentric circles; 3) the primary transmission achieves the maximum rate when the RIS only assists the primary transmission and the PTx transmits Gaussian signals; 4) the number of sum-rate-optimal points on the capacity region boundary is infinite which is achieved by the joint design of distributions of transmitted signals; 5) for the rate pairs with the maximum sum rate, the optimal distribution of the amplitude of the primary signal is a continuous Rayleigh distribution, while for the remaining rate pairs on the boundary, the optimal amplitude of the primary signal is discrete; 6) the adjustment of the amplitude for the RIS can increase the degree-of-freedom of the secondary transmission and enlarge the capacity region. In a nutshell, the main contributions of this paper are summarized as follows.

- We derive the optimal distributions of transmitted signals to achieve the maximum achievable rates for both primary and secondary transmissions as well as their maximum sum rate.
- We derive the optimal distributions of transmitted signals for the rate pairs on the boundary of capacity region and characterize capacity region of RIS-assisted SR.
- Extensive numerical results are provided to evaluate the performance of RIS-assisted SR and demonstrate the features of M-MAC.

The rest of the paper is organized as follows. In Section II, we establish the system model and represent the capacity region mathematically for RIS-assisted SR. The capacity regions for RIS-assisted SR for different passive reflection constraints are characterized in Sections III and IV, respectively. The performance evaluation is presented in Section V. Finally, the paper is concluded in Section VI.

Notations used in this paper are listed as follows. The lowercase and boldface lowercase x and \mathbf{x} denote a scalar variable (or constant) and a vector, respectively. $\mathcal{CN}(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ denotes the complex Gaussian distribution with mean $\boldsymbol{\mu}$ and variance $\boldsymbol{\Sigma}$. U(a, b) denotes the uniform distribution between the interval (a, b). \mathbf{x}^H denotes the conjugate transpose of \mathbf{x} . $\mathbb{E}(\cdot)$ denotes the statistical expectation. $cl(conv(\mathcal{A}))$ denotes the closure of the convex hull of a subset \mathcal{A} . $diag(\mathbf{x})$ denotes a diagonal matrix whose diagonal elements are given by the vector \mathbf{x} . $\delta(\cdot)$ stands for the Dirac- δ function. $\mathcal{L}(\cdot)$ and $\mathcal{L}^{-1}(\cdot)$ denote Laplace transform and inverse Laplace transform, respectively.

II. RIS-ASSISTED SR

In this section, we will describe the system model of RISassisted SR and illustrate mathematically the definition of capacity region for the RIS-assisted SR system.

A. System Model

The RIS-assisted SR system consists of a single-antenna PTx, a single-antenna cooperative receiver (C-Rx), and an RIS equipped with K reflecting elements. The PTx is an active device with maximum average power P, whose transmitted signal $X_1 \in \mathbb{C}$ satisfies an average power constraint $\mathbb{E}[|X_1|^2] \leq P$. The RIS is a passive device, which transmits signal $X_2 \in \mathbb{C}$ by periodically adjusting its reflection coefficients, i.e., $\phi = [\phi_1, \dots, \phi_K]^T$. The mapping between ϕ and X_2 is given by $\phi = \rho \varphi X_2$, where ρ is reflection efficiency with $\rho \leq 1$ and $\varphi = [\varphi_1, \dots, \varphi_K]^T$ is used for passive beamforming.

It is worth noting that the reflection coefficients of RIS should meet the passive reflection constraint due to the reflection nature of RISs. Typically, the reflection coefficients follow a phase shift model, where only the phase of each reflection coefficient is adjustable. In this case, to normalize X_2 , we have $|\varphi_k| = 1, \forall k$ and $|X_2| = 1$. On the other hand, we notice that some works point out that the amplitude of each reflection coefficient can also be adjusted [41]–[43], yielding the passive reflection constraint $|X_2| \leq 1$. As will hereafter be seen, the adjustment of the amplitude of reflection coefficients will increase the degree-of-freedom of the secondary transmission. Thus, in this paper, we will characterize capacity regions with constraint $|X_1| = 1$ and constraint $|X_1| \leq 1$, respectively.

Since capacity regions with and without the direct link from PTx to C-Rx for RIS-assisted SR are different, in this paper, we focus on the case where the direct link is blocked. The capacity region characterization with the direct link for RIS-assisted SR will be investigated in another paper. As shown in Fig. 1, denote by $\mathbf{v} = [v_1, \dots, v_K]^T \in \mathbb{C}^{K \times 1}$ the channel coefficient from the PTx to the RIS, and by $\mathbf{g}^H = [g_1, \dots, g_K] \in \mathbb{C}^{1 \times K}$ the channel coefficient from the RIS to the C-Rx. The received signal Y at the C-Rx is given by

$$Y = \rho \mathbf{g}^{H} \boldsymbol{\Psi} \mathbf{v} X_{1} X_{2} + Z$$
$$= h X_{1} X_{2} + Z, \tag{1}$$

where $h \triangleq \rho \mathbf{g}^H \Psi \mathbf{v}$, $\Psi = \text{diag}(\varphi)$, and $Z \sim \mathcal{CN}(0, \sigma^2)$ is the additive white Gaussian noise at the C-Rx. We assume the channel state information (CSI) is perfectly known to the transmitters and the receiver.

B. Definition of Capacity Region

Denote by R_1 and R_2 the achievable rates of primary and secondary transmissions, respectively. Under a low enough average error probability, the capacity region of M-MAC is the closure of the convex hull of all rate pairs (R_1, R_2) , which is denoted by C_{M-MAC} [34]. Following standard approaches in [34], the capacity region of M-MAC in RIS-assisted SR is characterized as

$$C_{\text{M-MAC}}(R_1, R_2) = \operatorname{cl}\left(\operatorname{conv}\left(\bigcup_{\varphi, f_1(X_1), f_2(X_2)} \mathcal{R}(R_1, R_2; \varphi, X_1, X_2)\right)\right), \quad (2)$$

Fig. 1: System model.

where $f_1(X_1)$ and $f_2(X_2)$ are the probability density functions (PDFs) of X_1 and X_2 , respectively, and $\mathcal{R}(R_1, R_2; \varphi, X_1, X_2)$ is the set of all tuples (R_1, R_2) satisfying:

$$R_1 \le I(X_1; Y | X_2, Q),$$
 (3)

$$R_2 \le I(X_2; Y | X_1, Q), \tag{4}$$

$$R_1 + R_2 \le I(X_1, X_2; Y, Q).$$
(5)

Note that Q is the time-sharing random variable, which will be discussed in the next section.

III. CAPACITY REGION CHARACTERIZATION WITH CONSTRAINT $|X_2| = 1$

In this section, we will characterize the capacity region of RIS-assisted SR with constraint $|X_2| = 1$. First, based on the definition of capacity region, we characterize the maximum achievable rates of primary and secondary transmissions as well as their maximum sum rate. Then, we describe rate pairs on the boundary of capacity region.

A. Maximum Achievable Rate of Primary Transmission

The maximum achievable rate of the primary transmission is denoted by C_1 , which can be obtained by solving the following problem:

$$\max_{\varphi, f_1(X_1), f_2(X_2)} I(X_1; Y | X_2)$$
(6)

s.t.
$$\mathbb{E}[|X_1|^2] < P \tag{7}$$

$$|X_2| = 1$$
 (8)

$$|\varphi_k| = 1, \forall k. \tag{9}$$

Given
$$\varphi$$
, for any distributions $f_1(X_1)$ and $f_2(X_2)$, we have

$$I(X_1; Y|X_2) = \int_{X_2} f_2(X_2) I(X_1; Y|X_2 = x_2) dx_2$$

$$\leq \max_{x_2} I(X_1; Y|X_2 = x_2), \quad (10)$$

since the average is less than the maximum. That means when the RIS purely assists the primary transmission, the primary transmission rate achieves the maximum.

Under average power constraints, Gaussian distribution can achieve the maximal entropy over all distributions [34]. Thus, when $X_1 \sim C\mathcal{N}(0, P)$, the primary transmission can achieve the maximum rate, which is given by

$$C_1 = \max_{\varphi, x_2} \log\left(1 + \frac{P|hx_2|^2}{\sigma^2}\right).$$
 (11)

From (11), when $|hx_2|^2$ is maximized, the primary transmission can achieve the maximum rate, whose solution is $\varphi_k x_2 = e^{\vartheta - j \arg(v_k g_k)}$ and ϑ is an arbitrary value from $-\pi$ to π . By defining $\tilde{h} = \sum_{k=1}^{K} \rho |v_k g_k|$, we have

$$C_1 = \log\left(1 + \frac{P\tilde{h}^2}{\sigma^2}\right). \tag{12}$$

B. Maximum Achievable Rate of Secondary Transmission

In this section, we will provide the maximum achievable rate of the secondary transmission, which is denoted by C_2 and can be obtained by solving the following problem:

$$\max_{\varphi, f_1(X_1), f_2(X_2)} I(X_2; Y | X_1)$$

s.t. (7), (8), and (9).

Based on the definition of mutual information, we have

$$I(X_2; Y|X_1) = \int_{X_1} f_1(X_1) I(X_2; Y|X_1 = x_1) dx_1.$$
(13)

According to [44], the optimal distribution of $f_2(X_2)$ to maximize $I(X_2; Y|X_1 = x_1)$ is characterized by a uniformly distributed independent phase from $-\pi$ to π , i.e., $X_2 = e^{j\theta_2}$ and $\theta_2 \sim U[-\pi, \pi)$.

Theorem 1: The mutual information $I(X_2; Y|X_1 = x_1)$ can be calculated by

$$I(X_2; Y|X_1 = x_1) = -\int_0^{+\infty} \frac{2r\kappa(r)}{\sigma^2} \log\left(\kappa(r)\right) dr - \log(e),$$
(14)
where $\kappa(r) = \exp\left(-\frac{r^2 + |hx_1|^2}{\sigma^2}\right) I_0\left(\frac{2r|hx_1|}{\sigma^2}\right)$ and $I_0(x) = \frac{1}{2\pi} \int_0^{\pi} e^{x\cos\theta} d\theta.$

Proof: Please see Appendix A.

An asymptotic behavior of (14) is given by [44]

$$I(X_2; Y|X_1 = x_1) \approx \begin{cases} \frac{1}{2} \log\left(\frac{4\pi |hx_1|^2}{e\sigma^2}\right), & \frac{|hx_1|^2}{\sigma^2} \gg 1, \\ \frac{|hx_1|^2}{\sigma^2}, & \frac{|hx_1|^2}{\sigma^2} \ll 1. \end{cases}$$
(15)

From (15), one can find that $I(X_2; Y|X_1 = x_1)$ is a monotonically increasing function of the receive signal-tonoise ratio (SNR), i.e., $\frac{|hx_1|^2}{\sigma^2}$. Thus, φ can be designed to maximize $|h|^2$, whose solution is $\varphi_k = e^{j(\vartheta - \arg(v_k g_k))}$, where ϑ is an arbitrary value from $-\pi$ to π .

We next discuss the optimal distribution of X_1 to maximize $I(X_2; Y|X_1)$. From (15), it is obvious that $I(X_2; Y|X_1 = x_1)$ a concave function over $|x_1|^2$. Since the phase of X_1 does not affect $I(X_2; Y|X_1 = x_1)$ from (14) and (15), then based on Jensen's inequality, we have

$$I(X_2; Y|X_1) = \mathbb{E}_{x_1} I(X_2; Y|X_1 = x_1)$$

$$\leq I(X_2; Y||X_1|^2 = P).$$
(16)

Thus, when $|X_1|^2 = P$, the maximum rate is achievable for the secondary transmission. Note that the phase of X_2 follows a uniform distribution over $[-\pi, \pi)$. To avoid information ambiguity, the PTx is required to transmit a sinusoidal signal without phase information to maximize the achievable rate of the secondary transmission.

Given $f_2(X_2)$, $X_1 = \sqrt{P}$, and $\varphi_k = e^{j(\vartheta - \arg(v_k g_k))}$, the maximum achievable rate of the secondary transmission is given by

$$C_2 = -\int_0^{+\infty} \frac{2r\underline{\kappa}(r)}{\sigma^2} \log\left(\underline{\kappa}(r)\right) dr - \log(e), \qquad (17)$$

where $\underline{\kappa}(r) = \exp\left(-\frac{r^2 + P\tilde{h}^2}{\sigma^2}\right) I_0\left(\frac{2r\sqrt{P}\tilde{h}}{\sigma^2}\right)$. An asymptotic behavior of (17) is given by [44]

$$C_2 \approx \begin{cases} \frac{1}{2} \log \left(\frac{4\pi P \tilde{h}^2}{e \sigma^2} \right), & \frac{P \tilde{h}^2}{\sigma^2} \gg 1, \\ \frac{P \tilde{h}^2}{\sigma^2}, & \frac{P \tilde{h}^2}{\sigma^2} \ll 1. \end{cases}$$
(18)

From (17) and (18), one can see that the PTx serves as an energy source for the RIS to transmit information, which is equivalent to a system where a transmitter transmits messages $\sqrt{P}e^{j\theta_2}$ with channel \tilde{h} , where $\theta_2 \sim U[-\pi,\pi)$. Since under average power constraints, Gaussian distribution achieves the maximal entropy over all distribution, we know that the maximum achievable rate of the secondary transmission C_2 is less than C_1 .

C. Maximum Achievable Sum Rate

The maximum achievable sum rate of the primary and secondary transmissions is denoted by C_{sum} , which is obtained by solving the following problem:

$$\max_{\substack{\varphi, f_1(X_1), f_2(X_2)}} I(X_1, X_2; Y)$$

s.t. (7), (8), and (9).

To characterize the maximum sum rate, we consider another transmission case where (X, 1) are symbols transmitted at the PTx and RIS, respectively, with $X = X_1X_2$. In this case, the PTx transmits two independent messages at a total rate I(X;Y) and the RIS does not transmit messages. Compared with the case where (X_1, X_2) are symbols transmitted at the PTx and RIS, respectively, the C-Rx receives the same messages. Thus, the above two transmission cases are equivalent for the C-Rx such that $I(X_1, X_2; Y) = I(X;Y)$. Therefore, maximizing $I(X_1, X_2;Y)$ is equivalent to maximizing I(X;Y).

Due to $\mathbb{E}[|X_1|^2] \leq P$ and $|X_2| = 1$, the signal X should satisfy the average power constraint, i.e, $\mathbb{E}[|X|^2] = \mathbb{E}[|X_1X_2|^2] \leq P$. According to [34], under the average power constraint, when $X \sim \mathcal{CN}(0, P)$ and $\varphi_k = e^{j(\vartheta - \arg(v_k g_k))}$, I(X;Y) achieves the maximum, which is given by

$$C_{\rm sum} = \log(1 + \frac{P\tilde{h}^2}{\sigma^2}). \tag{19}$$

This indicates that when $X_1X_2 \sim C\mathcal{N}(0, P)$, the RIS-assisted SR can achieve the maximum sum rate. There are infinite distributions for X_1 and X_2 to achieve $X_1X_2 \sim C\mathcal{N}(0, P)$, which will be discussed in Section III-D.

In the above subsections, we have characterized the maximum achievable rates of primary and secondary transmissions

Fig. 2: Structure of capacity region of RIS-assisted SR.

as well as their maximum sum rate. We know that the maximum sum rate is equal to the maximum achievable rate of the primary transmission and is greater than the maximum achievable rate of the secondary transmission. Based on these features, we plot the capacity region structure of RIS-assisted SR, as shown in Fig. 2. Rate pairs on boundary A-B can achieve the maximum sum rate, which will be discussed in Section III-D, while rate pairs on boundary B-C can not achieve the maximum sum rate and present variations from the maximum sum rate to the maximum achievable rate of the secondary transmission, which will be discussed in Section III-E.

D. Rate Pairs on Boundary A-B

From Section III-C, the maximum sum rate is achievable when $X_1X_2 \sim C\mathcal{N}(0, P)$. Since the amplitude of X_2 is equal to one, the amplitude of X_1 should follow a Rayleigh distribution to realize $X_1X_2 \sim C\mathcal{N}(0, P)$. There are infinite distributions for the phases of X_1 and X_2 to realize $X_1X_2 \sim C\mathcal{N}(0, P)$, which can be summarized as:¹

- Scheme I: The phase of X₁ follows a uniform distribution over [-α, α), i.e., θ₁ ~ U[-α, α). The phase of X₂ follows α/π Σ_n δ(θ₂ 2nα), where n = 0, 1, · · · , π/α 1. Note that α needs to be carefully chosen such that π/α is a positive integer and α ≠ 0.
- (2) Scheme II: The phase of X₂ follows a uniform distribution over [-α, α), i.e., θ₂ ~ U[-α, α). The phase of X₁ follows ^α/_π Σ_n δ(θ₁-2nα), where n = 0, · · · , ^π/_α 1, and ^π/_α is a positive integer with α ≠ 0.

With scheme I and scheme II, the phase of X_1X_2 is uniformed distributed over $[-\pi,\pi)$. Fig. 3 shows examples of the phase PDFs of X_1 , X_2 , and X for schemes I and II with $\alpha = \frac{\pi}{2}$. By going through α from 0 to π and holding $\frac{\pi}{\alpha}$ be a positive integer for schemes I and II, we can obtain different rate pairs on boundary **A-B** with the maximum sum rate, which are given by Theorem 2.

Fig. 3: Examples of the phase PDFs of X_1 , X_2 , and X.

Theorem 2: With the input distributions described in schemes I and II, the mutual information with a given decoding order can be calculated by

$$\begin{split} I(X_i;Y) &= \log(\pi e(P\tilde{h}^2 + \sigma^2)) + \mathbb{E}_{x_i} \int_0^{+\infty} \int_{-\pi}^{\pi} \kappa_{i,w}(r,\psi,x_i) \\ &\times \log(\frac{\kappa_{i,w}(r,\psi,x_i)}{r}) d\psi dr, \\ I(X_{t,t\neq i};Y|X_i) &= -\mathbb{E}_{x_i} \int_0^{+\infty} \int_{-\pi}^{\pi} \kappa_{i,w}(r,\psi,x_i) \\ &\times \log(\frac{\kappa_{i,w}(r,\psi,x_i)}{r}) d\psi dr - \log(\pi e \sigma^2), \end{split}$$

where $t, i \in \{1, 2\}$, $w \in \{1, 2\}$, and $\kappa_{i,w}(r, \psi, x_i)$ for $i \in \{1, 2\}$ and $w \in \{1, 2\}$ are given by

- 1) when decoding X_1 first with scheme I, we have $\kappa_{1,1}(r,\psi,x_1) = \sum_{n=0}^{\frac{\pi}{\alpha}-1} \frac{r\alpha}{\pi^2 \sigma^2} \exp\left(-\frac{r^2+\tilde{h}^2|x_1|^2-2r\tilde{h}|x_1|\cos(\theta_1+2n\alpha-\psi)}{\sigma^2}\right);$
- 2) when decoding with X_2 first scheme I. $\int_{-\alpha}^{\alpha} \frac{r|x_1|}{2P\alpha\pi^2\sigma^2}$ \int_0^+ we have $\kappa_{2,1}(r,\psi,x_2)$ = $-\frac{r^2 + \tilde{h}^2 |x_1|^2 - 2r\tilde{h} |x_1| \cos(\theta_1 + \theta_2)}{r^2 + \tilde{h}^2 |x_1|^2 - 2r\tilde{h} |x_1| \cos(\theta_1 + \theta_2)}$ $\psi)$ $d\theta_1 d|x_1|;$ exp
- 3) when decoding X_1 first with scheme II, we have $\kappa_{1,2}(r,\psi,x_1) = \int_{-\alpha}^{\alpha} \frac{r}{2\alpha\pi\sigma^2} \exp\left(-\frac{r^2+\tilde{h}^2|x_1|^2-2r\tilde{h}|x_1|\cos(\theta_1+\theta_2-\psi)}{\sigma^2}\right) d\theta_2;$
- 4) when decoding X_2 first with scheme II, we have $\kappa_{2,2}(r,\psi,x_2) = \int_0^{+\infty} \sum_{n=0}^{\frac{\pi}{\alpha}-1} \frac{r|x_1|\alpha}{P\pi^3\sigma^2} \exp\left(-\frac{|x_1|^2}{P} \frac{r^2 + \tilde{h}^2 |x_1|^2 2r\tilde{h} |x_1| \cos(2n\alpha + \theta_2 \psi)}{\sigma^2}\right) d|x_1|.$ *Proof:* Please see Appendix B.

For scheme I, when $\alpha = \pi$, RIS does not transmit information and only assists the primary transmission by passive beamforming, i.e., $X_2 = 1$ and $X_1 \sim C\mathcal{N}(0, P)$. For scheme

¹When $\theta_1 \sim U[-\pi,\pi)$ and $\theta_2 \sim U[-\pi,\pi)$, we also have $X \sim U[-\pi,\pi)$. However, in this case, the phase information of X_1 and X_2 is coupled together and may cause information ambiguity. Thus, in this paper, we do not consider this scenario.

II, when $\alpha = \pi$, the PTx only transmits the amplitude signal following Rayleigh distribution while the RIS transmits the phase signal following uniform distribution over $[-\pi, \pi)$. It should be noted that with $\alpha = \pi$ for scheme II, when X_1 is decoded first, $I(X_2; Y|X_1)$ achieves the maximum under the condition of the maximum sum rate. Hence, the corresponding rate pair is the corner point **B** in Fig. 2.

The rate pairs characterized by Theorem 2 are some discrete points on boundary A-B. The other rate pairs on boundary A-B can be achieved by time sharing. In this case, the cardinality of the time-sharing random variable is $|Q| \leq 2$ according to [45, Appendix 4A].

E. Rate Pairs on Boundary B-C

To characterize boundary B-C, we need to further increase the rate of the secondary transmission. Since the capacity region is the convex hull of rate pairs (R_1, R_2) , boundary B-C of the capacity region can be characterized by maximizing $\mu_1 R_1 + \mu_2 R_2$ over all rate pairs, where (μ_1, μ_2) are nonnegative and satisfy $\mu_1 + \mu_2 = 1$ and $\mu_2 > \mu_1$ [46]. Since the user with the lower priority will be decoded first, the maximization of $\mu_1 R_1 + \mu_2 R_2$ can be written as $\mu_1 I(X_1; Y) + \mu_2 I(X_2; Y|X_1)$ [46]. Then, the rate pairs on boundary B-C can be obtained by solving the following optimization problem.

P1:
$$\max_{\boldsymbol{\varphi}, f_1(X_1), f_2(X_2)} \mu_1 I(X_1; Y) + \mu_2 I(X_2; Y | X_1)$$

s.t. (7), (8), and (9).

Since the stronger channel response enables higher achievable rates of primary and secondary transmissions, φ can be designed to maximize $|h|^2$, whose solution is $\varphi_k = e^{j(\vartheta - \arg(v_k g_k))}$. Then, we focus on the optimal distributions of X_1 and X_2 . The objective function can be written as

$$\mu_1 I(X_1; Y) + \mu_2 I(X_2; Y|X_1) = \mu_1 H(Y) - \mu_1 H(Y|X_1) + \mu_2 H(Y|X_1) - \mu_2 H(Y|X_1, X_2) = \mu_1 H(Y) + (\mu_2 - \mu_1) H(Y|X_1) - \mu_2 H(Y|X_1, X_2).$$

The maximization of H(Y) requires $\theta_1 + \theta_2 \sim U[-\pi, \pi)$, while the maximization of $H(Y|X_1)$ requires $\theta_2 \sim U[-\pi, \pi)$, which has been discussed in Sections III-A and III-B. Due to $\mu_2 - \mu_1 > 0$, it is obvious that the optimal distribution of $f_2(X_2)$ is characterized by a uniformly distributed independent phase from $-\pi$ to π , while the PTx only transmits amplitude information. Accordingly, the PDF of X_1 is given by $f_1(X_1) = f_a(A)\delta(\theta_1)$, where A is the amplitude of X_1 and $f_a(A)$ is the PDF of A. Then, the optimization problem **P1** can be recast as

$$\begin{aligned} \mathbf{P2}: & \max_{f_a} & \mu_1 H(Y) + (\mu_2 - \mu_1) H(Y|A) \\ & \text{s.t.} & \int_0^\infty f_a a^2 da \leq P. \end{aligned}$$

Here, we introduce the marginal entropy induced by f_a , which is given by

$$\omega(A; f_a) = -\int f_y(Y|A) \log f_y(Y; f_a) dy, \qquad (20)$$

where $f_y(Y|A)$ is the PDF of Y given A and $f_y(Y; f_a)$ is the PDF of Y with f_a . The following theorem provides the properties of the optimal f_a in problem **P2**.

Theorem 3: The optimal distribution of A is denoted by f_a^* . Then, f_a^* is optimal if and only if

$$\omega(A; f_a^*) \le T_0 - \left(\frac{\mu_2}{\mu_1} - 1\right) H(Y|A = a) + \frac{\lambda}{\mu_1} a^2, \ \forall a \ (21)$$
$$\omega(A; f_a^*) = T_0 - \left(\frac{\mu_2}{\mu_1} - 1\right) H(Y|A = a) + \frac{\lambda}{\mu_1} a^2, \ \forall a \in E_0,$$
(22)

where $\lambda \geq 0$ is a Lagrange multiplier, T_0 is a constant value and equal to $\int_0^\infty f_a^* \omega(A; f_a^*) da + (\frac{\mu_2}{\mu_1} - 1) \int_0^\infty f_a^* H(Y|A = a) da - \frac{\lambda}{\mu_1} P$, and E_0 is the points of increase of the cumulative distribution function (CDF) F_a^* that corresponds to f_a^* .

Proof: Please see Appendix C.

From Appendix D, the increase points set E_0 of the optimal CDF F_a^* is finite. Thus, the optimal PDF f_a^* can be written as

$$f_a^*(A) = \sum_{m=1}^{M} p_m \delta(A - a_m),$$
 (23)

where $\sum_{m=1}^{M} p_m a_m^2 \leq P$, $a_{m+1} > a_m$, $0 \leq p_m \leq 1$, and $\sum_{m=1}^{M} p_m = 1$. Meanwhile, M is the number of mass points, a_m is the location of the *m*-th mass point, and p_m is the corresponding probability of the *m*-th mass point. Note that the number, location, and probability of mass points in (23) should satisfy the conditions in Theorem 3.

With $f_a^*(A)$ in (23), according to Appendix E, the achievable rates for both primary and secondary transmissions are given, respectively, by

$$I(X_{1};Y) = \sum_{m=1}^{M} p_{m} \int_{0}^{+\infty} \frac{2r\bar{\kappa}(r,a_{m})}{\sigma^{2}} \log\left(\bar{\kappa}(r,a_{m})\right) dr$$
$$-\int_{0}^{+\infty} \frac{\sum_{m=1}^{M} 2rp_{m}\bar{\kappa}(r,a_{m})}{\sigma^{2}} \log\left(\sum_{m=1}^{M} p_{m}\bar{\kappa}(r,a_{m})\right) dr, \quad (24)$$
$$I(X_{2};Y|X_{1}) = -\sum_{m=1}^{M} p_{m} \int_{0}^{+\infty} \frac{2r\bar{\kappa}(r,a_{m})}{\sigma^{2}}$$
$$\times \log\left(\bar{\kappa}(r,a_{m})\right) dr - \log(e), \quad (25)$$

where $\bar{\kappa}(r,a_m) = \exp\left(-\frac{r^2 + \tilde{h}^2 a_m^2}{\sigma^2}\right) I_0\left(\frac{2r\tilde{h}a_m}{\sigma^2}\right)$. Although we prove that the optimal distribution of the

Although we prove that the optimal distribution of the amplitude of X_1 of rate pairs on boundary **B**-**C** is discrete, a closed-form solution of f_a^* with specific M, p_m , and a_m seems unlikely. On one hand, the optimal M, p_m , and a_m can be obtained by using the scheme proposed in [36], which solves f_a^* based on the conditions in (21) and (22). On the other hand, the optimal M, p_m , and a_m can be obtained by solving the following optimization problem directly:

P3:
$$\max_{M, a_m, p_m} \mu_1 I(X_1; Y) + \mu_2 I(X_2; Y | X_1)$$

s.t.
$$\sum_{m=1}^M p_m a_m^2 \le P, \quad a_{m+1} > a_m$$
$$0 \le p_m \le 1, \quad \sum_{m=1}^M p_m = 1.$$

Fig. 4: An example of the optimal input distribution with passive reflection constraint.

Note that the objective function in problem **P3** can be explicitly represented by (24) and (25). For problem **P3**, the variables M, a_m , and p_m are coupled together in the objective function. Thus, the objective function is not concave over M, a_m , and p_m . Meanwhile, one can find that the constraint $\sum_{m=1}^{M} p_m a_m^2 = P$ is not a convex set. Thus, problem **P3** is a non-convex optimization problem and belongs to nonlinear programming. Nonetheless, it can be solved by using an interior-point algorithm, which introduces barrier functions to deal with inequality constraints and adopts conjugate gradient methods to find a convergence point [47]. Due to space limitations, we omit the details of interior-point algorithms.

IV. CAPACITY REGION CHARACTERIZATION WITH CONSTRAINT $|X_2| \le 1$

In this section, we will characterize the capacity region with constraint $|X_2| \leq 1$. Following the derivations in Section III, one can find that the adjustment of the amplitude will not affect the maximum achievable rate of the primary transmission and the maximum sum rate. Thus, in the following, we will focus on the maximum achievable rate of the secondary transmission and the rate pairs on boundary **B**-C.

A. Maximum Achievable Rate of Secondary Transmission

Mathematically, the capacity under passive reflection constraint $|X_2| \leq 1$ is equivalent to that under a peak power constraint $|X_2|^2 \leq 1$. Thus, the optimal distribution to maximize $I(X_2; Y|X_1 = x_1)$ is geometrically characterized by concentric circles, i.e., discrete amplitude and uniform independent phase, as shown in Fig. 4 [37]. Denote the amplitude of X_2 by r, whose PDF f_r is given by

$$f_r(r) = \sum_{\ell=1}^{L} q_\ell \delta(r - r_l), \qquad (26)$$

with $0 \le r_{\ell} \le 1$, $r_{\ell+1} > r_{\ell}$, $0 \le q_{\ell} \le 1$, and $\sum_{\ell=1}^{L} q_{\ell} = 1$. Meanwhile, *L* is the number of mass points, r_l is the location of the ℓ -th mass point, and q_{ℓ} is the corresponding probability of the ℓ -th mass point. Note that the number of mass points and the corresponding locations and probabilities are determined by maximizing the mutual information of the secondary transmission.

Following the derivations in Appendix A, we know that under constraint $|X_1| \leq 1$, the mutual information

 $I(X_2; Y|X_1 = x_1)$ has the same expression with (14) but with $\kappa(r) = \sum_{\ell=1}^{L} q_\ell \exp\left(-\frac{r^2 + |hx_1|^2 r_\ell^2}{\sigma^2}\right) I_0\left(\frac{2r|hx_1|r_\ell}{\sigma^2}\right)$. Considering the complexity of the expression of $I(X_2; Y|X_1 = x_1)$, we provide an upper bound on $I(X_2; Y|X_1 = x_1)$, which is given by [48]

$$I(X_{2}; Y|X_{1} = x_{1}) \leq \min\left\{\log\left(1 + \frac{\tilde{h}^{2}|x_{1}|^{2}}{\sigma^{2}}\right), \\ \log\left(1 + \sqrt{\frac{\pi\tilde{h}^{2}|x_{1}|^{2}}{\sigma^{2}}} + \frac{\tilde{h}^{2}|x_{1}|}{e\sigma^{2}}\right)\right\}.$$
 (27)

In (27), the first part in the min function represents the capacity relaxed to an average power constraint and the second part represents the McKellips-type bound. At low $\frac{\tilde{h}^2|x_1|^2}{\sigma^2}$, $I(X_2; Y|X_1 = x_1)$ approaches the first part in (27), while approaches the second part at high $\frac{\tilde{h}^2|x_1|^2}{\sigma^2}$.

Following the derivations in Section III-A, we know that the optimal passive beamforming of RIS is $\varphi_k = e^{j(\vartheta - \arg(v_k g_k))}$ and the primary transmission satisfies $|X_1|^2 = P$ to maximize the achievable rate of the secondary transmission. Then, the maximum achievable rate of the secondary transmission under constraint $|X_2| \le 1$ is given by

$$C_2 = \max_{L,p_l,r_l} -\int_0^{+\infty} \frac{2r\tilde{\kappa}(r)}{\sigma^2} \log\left(\tilde{\kappa}(r)\right) dr - \log(e), \quad (28)$$

where
$$\tilde{\kappa}(r) = \sum_{\ell=1}^{L} q_{\ell} \exp\left(-\frac{r^2 + P\tilde{h}^2 r_{\ell}^2}{\sigma^2}\right) I_0\left(\frac{2r\sqrt{P\tilde{h}}r_{\ell}}{\sigma^2}\right).$$

When the receive SNR $\frac{Pn^2}{\sigma^2}$ is low, the capacity-achieving distribution is geometrically characterized by a unit circle, i.e., the amplitude of X_2 is equal to 1. With the growth of $\frac{P\tilde{h}^2}{\sigma^2}$, the concentric circle number of the capacity-achieving distribution will increase. An upper bound on (28) is given by [48]

$$C_{2} \leq \min\left\{\log\left(1 + \sqrt{\frac{\pi P\tilde{h}^{2}}{\sigma^{2}}} + \frac{P\tilde{h}^{2}}{e\sigma^{2}}\right), \\ \log\left(1 + \frac{P\tilde{h}^{2}}{\sigma^{2}}\right)\right\}.$$
 (29)

It can be calculated that there is an SNR gap of about $10 \log_{10}(e) \approx 4.34$ dB at high receive SNR between the two parts in (29). This indicates that if we use $\log \left(1 + \frac{P\tilde{h}^2}{\sigma^2}\right)$ to analyze the performance of the secondary transmission, we will get a more than 4.34 dB performance gap at high receive SNR.

In addition, we can find that under constraint $|X_1| \leq 1$, the high SNR slope is $\lim_{P\to\infty} \frac{C_2}{\log P} = 1$, while under constraint $|X_1| = 1$, the high SNR slope becomes $\lim_{P\to\infty} \frac{C_2}{\log P} = \frac{1}{2}$. This indicates that if RIS only transmits the phase information, the degree-of-freedom of the secondary transmission will be halved.

B. Rate Pairs on Boundary B-C

With constraint $|X_1| \leq 1$, the rate pairs on boundary **B**-C can also be characterized by solving **P1**. It is obvious that the design of the passive beamforming vector is the same as the

Fig. 5: The optimized locations of the mass points versus the corresponding probabilities of f_a^* with constraint $|X_2| = 1$.

case with $|X_1| = 1$ such that the optimization problem **P1** can be written as

P4:
$$\max_{f_1(X_1), f_2(X_2)} \mu_1 H(Y) + (\mu_2 - \mu_1) H(Y|X_1)$$

s.t. (7) and $|X_1| \le 1$.

With the same reason as the case $|X_2| = 1$, $|X_2|$ is characterized by a uniformly distributed independent phase from $-\pi$ to π , while the PTx only transmits amplitude information.

From Appendix F, the optimal amplitude PDFs of both X_1 and X_2 are discrete and given by (23) and (26), respectively. Thus, we can derive the mutual information $I(X_1;Y)$ and $I(X_2;Y|X_1)$, which have the same expressions with (24) and (25), respectively, but with $\bar{\kappa}(r, a_m) = \sum_{\ell=1}^{L} q_\ell \exp\left(-\frac{r^2 + \tilde{h}_2^2 a_m^2 r_\ell^2}{\sigma^2}\right) I_0\left(\frac{2r \tilde{h}_2 a_m r_\ell}{\sigma^2}\right)$.

Note that the number, location, and probability of mass points in (23) and (26) can be obtained by solving the following optimization problem:

$$\begin{aligned} \mathbf{P5}: & \max_{L,M,r_{\ell},a_m,q_{\ell},p_m} & \mu_1 I(X_1;Y) + \mu_2 I(X_2;Y|X_1) \\ & \text{s.t.} & 0 \leq r_l \leq 1, \quad r_{\ell+1} > r_l, \\ & 0 \leq q_l \leq 1, \quad \sum_{\ell=1}^L q_\ell = 1, \\ & \sum_{m=1}^M p_m a_m^2 \leq P, \quad a_{m+1} > a_m \\ & 0 \leq p_m \leq 1, \quad \sum_{m=1}^M p_m = 1. \end{aligned}$$

Similar to problem **P3**, problem **P5** can be solved by using an interior-point algorithm [47].

V. PERFORMANCE EVALUATION

In this section, numerical results are presented to evaluate the capacity region of RIS-assisted SR. Since the stronger reflecting link represents the higher receive SNR, the effect of Kon the performance of primary and secondary transmissions is equivalent to the effect of $\frac{P}{\sigma^2}$. Thus, unless specified otherwise, we set K = 64 and $\rho^2 |g_k v_k|^2 = 0.003$, for $k = 1, \dots, K$. Problems **P3** and **P5** are solved by using the optimization package of Matlab [49].

Fig. 5 plots the optimized locations of the mass points versus the corresponding probabilities of f_a^* with constraint

Fig. 6: The optimized locations of the mass points versus the corresponding probabilities for the distributions of the primary and secondary transmissions with constraint $|X_2| \leq 1$.

 $|X_2| = 1$. In this figure, we set $P/\sigma^2 = 5$ dB. We can find that when $|X_2| = 1$, the number of mass points increases with the growth of μ_1 , and the probability of f_a^* approaches a Rayleigh distribution when $\mu_1 = 0.49$. Fig. 6 plots the optimized locations of the mass points versus the corresponding probabilities of the distributions for both the primary and secondary transmissions with constraint $|X_2| \leq 1$. We set $P/\sigma^2 = 5$ dB. Similar to Fig. 5, with the increase of μ_1 , the number of mass points of f_a^* increases. When $\mu_2 = 0.51$, the optimal X_2 is equal to $X_2 = e^{j\theta_2}$ and the optimal f_1^* approaches a Rayleigh distribution. This indicates that the rate pair when $\mu_2 = 0.51$ approaches point B on the region boundary.

In Fig. 7, the capacity region of RIS-assisted SR is plotted for different P/σ^2 with constraints $|X_2| = 1$ and $|X_1| \le 1$.

Fig. 8: Achievable rates versus transmit SNR, i.e., P/σ^2 .

We can see that the capacity region is always strictly convex. A higher average transmit power at the PTx can lead to a larger capacity region. It is obvious that constraint $|X_2| \leq 1$ enables a larger capacity region for RIS-assisted SR compared with constraint $|X_2| = 1$ when $\frac{P}{\sigma^2} = 0$ dB and $\frac{P}{\sigma^2} = 5$ dB. In addition, with the growth of $\frac{P}{\sigma^2}$, the gap between the capacity regions with constraints $|X_2| = 1$ and $|X_2| \leq 1$ enlarges. When $\frac{P}{\sigma^2} = -5$ dB, the characterized capacity regions with constraints $|X_2| = 1$ and $|X_2| \leq 1$ are the same. The main reason is that when the received SNR is low, the capacity-achieving distributions on boundary **B**-**C** are geometrically characterized by a unit circle for X_2 .

Fig. 8 demonstrates the achievable rates for both primary and secondary transmissions versus P/σ^2 . It can be found that the maximum achievable rate of the primary transmission is always greater than that of the secondary transmission, which is consistent with the analysis in Section III-B. Meanwhile, when $|X_2| \leq 1$, the upper bound on the capacity of the secondary transmission shown in (29) becomes tight when $\frac{P}{\sigma^2}$ is high. The slope of the upper bound is consistent with that of the capacity of the secondary transmission when $\frac{P}{\sigma^2}$ is high. In addition, the asymptotic results in (18) can fit well with the capacity of the secondary transmission given constraint $|X_2| = 1$. It is obvious that the slope of C_2 with $|X_2| \leq 1$ is two times that of C_2 with $|X_2| = 1$, which coincides with the analysis in Section IV.

VI. CONCLUSIONS

This paper has focused on the capacity region characterization for RIS-assisted SR when the direct link is blocked. The capacity-achieving distributions of the transmitted signals at PTx and RIS have been analyzed. Also, the maximum achievable rates for both primary and secondary transmissions as well as their maximum sum rate have been derived. Furthermore, capacity regions of RIS-assisted SR with two types of passive reflection constraints have been characterized. Finally, numerical results have been presented to evaluate the performance of RIS-assisted SR.

APPENDIX A

Based on the definition of mutual information, we have $I(X_2; Y|X_1 = x_1) = H(Y|X_1 = x_1) - H(X_2, X_1 = x_1)$. It is straightforward to have $H(Y|X_2, X_1 = x_1) = H(Z) = \log(\pi e \sigma^2)$. Then, we focus on the calculation of $H(Y|X_1 = x_1)$. The polar coordinates of Y is given by $(\bar{r}, \bar{\psi})$, where \bar{r} and $\bar{\psi}$ are the amplitude and the phase of Y, respectively. According to Jacobian of transformation in terms of PDF, we have $f_y(\bar{r}, \bar{\psi}|x_1) = \bar{r}p_y(\text{Re}(y), \text{Im}(y)|x_1)$, where p_y is the PDF of Y in the Cartesian coordinates. Hence, we have

$$H(Y|X_1 = x_1)$$

$$= \int_{\mathbb{C}} p_y(\operatorname{Re}(y), \operatorname{Im}(y)|x_1) \log(p_y(\operatorname{Re}(y), \operatorname{Im}(y)|x_1)) dy$$

$$\stackrel{(a)}{=} -\int_0^{+\infty} \int_{-\pi}^{\pi} \bar{r} p_y(\bar{r} \cos \bar{\psi}, \bar{r} \sin \bar{\psi}|x_1) \times \log(p_y(\bar{r} \cos \bar{\psi}, \bar{r} \sin \bar{\psi}|x_1) d\bar{\psi} d\bar{r}$$

$$= -\int_0^{+\infty} \int_{-\pi}^{\pi} f_y(\bar{r}, \bar{\psi}|x_1) \log(\frac{f_y(\bar{r}, \bar{\psi}|x_1)}{\bar{r}}) d\bar{\psi} d\bar{r},$$

where (a) follows from the Jacobian of transformation in terms of integration. The PDF of Y given X_1 in terms of the polar coordinates, i.e., $f_y(\bar{r}, \bar{\psi}|x_1)$, is given by

$$f_{y}(\bar{r},\bar{\psi}|x_{1}) = \bar{r}p_{y}(\bar{r}\cos\bar{\psi},\bar{r}\sin\bar{\psi}|x_{1})$$

$$=\bar{r}\int_{x_{2}}f_{2}(X_{2})p_{y}(\bar{r}\cos\bar{\psi},\bar{r}\sin\bar{\psi}|x_{1},x_{2})dx_{2}$$

$$=\int_{x_{2}}f_{2}(X_{2})\frac{\bar{r}}{\pi\sigma^{2}}\exp\left(-\frac{|\bar{r}e^{j\bar{\psi}}-hx_{1}x_{2}|^{2}}{\sigma^{2}}\right)dx_{2}$$

$$=\int_{-\pi}^{\pi}\frac{\bar{r}}{2\pi^{2}\sigma^{2}}\exp\left(-\frac{\bar{r}^{2}+|hx_{1}|^{2}}{\sigma^{2}}\right)$$

$$\times\exp\left(\frac{2\bar{r}|hx_{1}|\cos(\theta_{2}+\vartheta-\bar{\psi})}{\sigma^{2}}\right)d\theta_{2}$$

$$=\frac{\bar{r}}{\pi\sigma^{2}}\exp\left(-\frac{\bar{r}^{2}+|hx_{1}|^{2}}{\sigma^{2}}\right)I_{0}\left(\frac{2\bar{r}|hx_{1}|}{\sigma^{2}}\right)=\frac{\bar{r}\kappa(\bar{r})}{\pi\sigma^{2}},\quad(30)$$

where ϑ is the phases of h, $I_0(x) = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{x \cos \theta} d\theta$, and $\kappa(\bar{r}) \triangleq \exp\left(-\frac{\bar{r}^2 + |hx_1|^2}{\sigma^2}\right) I_0\left(\frac{2\bar{r}|hx_1|}{\sigma^2}\right)$. From (30), we can find that the PDF of $f_y(\bar{r}, \bar{\psi}|x_1)$ is irrelevant to the phase of X_1 and h. Then, the marginal density $f_y(\bar{r}|x_1)$ can be obtained by integrating $\bar{\psi}$ out of (30):

$$f_y(\bar{r}|x_1) = \int_{-\pi}^{\pi} f_y(\bar{r}, \bar{\psi}|x_1) d\bar{\psi} = \frac{2\bar{r}\kappa(\bar{r})}{\sigma^2}.$$
 (31)

From (30) and (31), it is easy to find that $f_y(\bar{r}, \bar{\psi}|x_1) = \frac{1}{2\pi} f_y(\bar{r}|x_1)$, which means that the amplitude and the phase of Y given X_1 are independent. Substituting (30) and (31) into $H(Y|X_1 = x_1)$, we have

$$H(Y|X_1 = x_1) = -\int_0^{+\infty} f_y(\bar{r}|x_1) \log \frac{f_y(\bar{r}|x_1)}{\bar{r}} d\bar{r} + \log(2\pi)$$
$$= -\int_0^{+\infty} \frac{2\bar{r}\kappa(\bar{r})}{\sigma^2} \log(\kappa(\bar{r})) d\bar{r} + \log(\pi\sigma^2).$$

Thus, the mutual information $I(X_2; Y|X_1 = x_1)$ is given by

$$I(X_2; Y | X_1 = x_1) = H(Y | X_1) - \log(\pi e \sigma^2)$$

= $-\int_0^{+\infty} \frac{2\bar{r}\kappa(\bar{r})}{\sigma^2} \log(\kappa(\bar{r})) d\bar{r} - \log(e)$

Therefore, Theorem 1 can be proved.

APPENDIX B

For scheme I, when decoding X_1 first, we have $I(X_1; Y) = H(Y) - H(Y|X_1)$. Due to $X_1X_2 \sim C\mathcal{N}(0, P)$, we have $H(Y) = \log(\pi e(P\tilde{h}^2 + \sigma^2))$. Next, we focus on the calculation of $H(Y|X_1)$, which is given by

$$H(Y|X_1) = -\mathbb{E}_{x_1} \int_0^{+\infty} \int_{-\pi}^{\pi} f_y(\bar{r}, \bar{\psi}|x_1) \log(\frac{f_y(\bar{r}, \bar{\psi}|x_1)}{\bar{r}}) d\bar{\psi} d\bar{r},$$

where $\kappa_{1,1}(\bar{r}, \bar{\psi}, x_1) \triangleq f_y(\bar{r}, \bar{\psi}|x_1)$ can be written as

Then, the mutual information of $I(X_1; Y)$ is given by

$$I(X_{1};Y) = \log(\pi e(P\tilde{h}^{2} + \sigma^{2})) + \mathbb{E}_{x_{1}} \int_{0}^{+\infty} \int_{-\pi}^{\pi} \kappa_{1,1}(\bar{r}, \bar{\psi}, x_{1}) \\ \times \log(\frac{\kappa_{1,1}(\bar{r}, \bar{\psi}, x_{1})}{\bar{r}}) d\bar{\psi} d\bar{r}.$$

Since $I(X_2; Y|X_1) = H(Y|X_1) - H(Y|X_1, X_2)$ and $H(Y|X_1, X_2) = \log(\pi e \sigma^2)$, we have

$$I(X_2; Y|X_1) = -\mathbb{E}_{x_1} \int_0^{+\infty} \int_{-\pi}^{\pi} \kappa_{1,1}(\bar{r}, \bar{\psi}, x_1) \\ \times \log(\frac{\kappa_{1,1}(\bar{r}, \bar{\psi}, x_1)}{\bar{r}}) d\bar{\psi} d\bar{r} - \log(\pi e \sigma^2).$$

The calculations of mutual information for scheme II and the other decoding order are similar to the above calculations and thus are omitted here.

APPENDIX C

Due to the multiplicative nature between X_1 and X_2 , the effect of unknown X_2 on mutual information is the same as that of the unknown channel state information. Thus, the structures of the existence proof below and Appendix D follow [50], but the details are different since the objective function in problem **P2** is more difficult to deal with. Considering the average power constraint of X_1 , according to Lagrangian Theorem, problem **P2** can be recast as

$$\min_{\lambda} \max_{f_a} \mu_1 H(Y) + (\mu_2 - \mu_1) H(Y|A) - \lambda \left(\int_0^\infty f_a a^2 da - P \right), \qquad (32)$$

where $\lambda \geq 0$ is a Laplace multiplier. Let T be a functional on a convex set \mathcal{F}_a , where $T(f_a^*) = \mu_1 H(Y; f_a^*) + (\mu_2 - \mu_1)H(Y|A; f_a^*) - \lambda \int_0^\infty f_a^* a^2 da$ with $f_a^* \in \mathcal{F}_a$. Then, the weak derivative of $T(f_a^*)$ is given by

$$T_{f_a^*}^{'}(f_a) = \lim_{\theta \to 0} \frac{T((1-\theta)f_a^* + \theta f_a) - T(f_a^*)}{\theta}$$

where $\theta \in [0,1]$ and f_a is an arbitrary PDF in \mathcal{F}_a . Define $f_a^{\theta} = (1-\theta)f_a^* + \theta f_a$, and then, we have

$$T(f_{a}^{\theta}) - T(f_{a}^{*}) = \mu_{1} \int_{0}^{+\infty} f_{a}^{\theta} \omega(a; f_{a}^{\theta}) da - \mu_{1} \int_{0}^{+\infty} f_{a}^{*} \omega(a; f_{a}^{*}) da + \int_{0}^{+\infty} (f_{a}^{\theta} - f_{a}^{*})((\mu_{2} - \mu_{1})H(Y|A = a) - \lambda a^{2}) da = \mu_{1} \int_{0}^{+\infty} f_{a}^{*}(\omega(a; f_{a}^{\theta}) - \omega(a; f_{a}^{*})) da + \theta \left(\int_{0}^{+\infty} (f_{a} - f_{a}^{*}) \right) \times (\mu_{1}\omega(a; f_{a}^{\theta}) + (\mu_{2} - \mu_{1})H(Y|A = a) - \lambda a^{2}) da).$$

Accordingly

$$T_{f_a^*}(f_a) = \int_0^{+\infty} (f_a - f_a^*)(\mu_1 \omega(a; f_a^*) + (\mu_2 - \mu_1)H(Y|A = a) - \lambda a^2)da.$$

According to [51], if T achieves its maximum at f_a^* , then we have $T'_{f_a}(f_a) \leq 0$ for all $f_a \in \mathcal{F}_a$, yielding

$$\int_{0}^{+\infty} f_{a} \left(\omega(a; f_{a}^{*}) + \left(\frac{\mu_{2}}{\mu_{1}} - 1\right) H(Y|A = a) - \frac{\lambda}{\mu_{1}} a^{2} \right) da$$

$$\leq \int_{0}^{+\infty} f_{a}^{*} \left(\omega(a; f_{a}^{*}) + \left(\frac{\mu_{2}}{\mu_{1}} - 1\right) H(Y|A = a) - \frac{\lambda}{\mu_{1}} a^{2} \right) da.$$
(33)

The right-hand side (RHS) of (33) can be represented by $T_0 = \int_0^\infty f_a^* \omega(a; f_a^*) da + (\frac{\mu_2}{\mu_1} - 1) \int_0^\infty f_a^* H(Y|A = a) da - \frac{\lambda}{\mu_1} P$. Note that if $\int_0^{+\infty} f_a^* a^2 da$ is less than P, λ is zero according to Karush–Kuhn–Tucker conditions, which indicates that (33) remains true.

We use contradictions to prove (21) in Theorem 3. If (21) is false, there exist an \tilde{a} such that

$$\omega(\tilde{a}; f_a^*) > T_0 - \left(\frac{\mu_2}{\mu_1} - 1\right) H(Y|A = \tilde{a}) + \frac{\lambda}{\mu_1} \tilde{a}^2.$$

Since (33) holds for all $f_a \in \mathcal{F}_a$, we assume $f_a = \delta(A - \tilde{a})$, where $\xi \triangleq \bar{r}^2$. and then we have

$$\int_{0}^{+\infty} f_a \left(\omega(a; f_a^*) + \left(\frac{\mu_2}{\mu_1} - 1\right) H(Y|A = a) - \frac{\lambda}{\mu_1} a^2 \right) da > T_0$$

which is contradicts (33). Thus, (21) is valid.

Then, we focus on the proof of (22) in Theorem 3, which can also be proved by contradictions. Specifically, we assume there exists $\tilde{a} \in E_0$ such that

$$\omega(\tilde{a}; f_a^*) < T_0 - \left(\frac{\mu_2}{\mu_1} - 1\right) H(Y|A = \tilde{a}) + \frac{\lambda}{\mu_1} \tilde{a}^2$$

Then, by using the definition of a point of increase of CDF, the neighborhood E of \tilde{a} satisfies $\int_{\tilde{E}} f_a^* da = \varrho > 0$. Hence, we have

$$\begin{split} T_{0} &= \int_{0}^{\infty} f_{a}^{*} \left(\omega(a; f_{a}^{*}) + \left(\frac{\mu_{2}}{\mu_{1}} - 1\right) H(Y|A = a) \right) da - \frac{\lambda}{\mu_{1}} P \\ &= \int_{\tilde{E}} f_{a}^{*} \left(\omega(a; f_{a}^{*}) + \left(\frac{\mu_{2}}{\mu_{1}} - 1\right) H(Y|A = a) \right) da \\ &+ \int_{E_{0} - \tilde{E}} f_{a}^{*} \left(\omega(a; f_{a}^{*}) + \left(\frac{\mu_{2}}{\mu_{1}} - 1\right) H(Y|A = a) \right) da - \frac{\lambda}{\mu_{1}} P \\ &< \varrho \left(T_{0} + \frac{\lambda}{\mu_{1}} P \right) + (1 - \varrho) \left(T_{0} + \frac{\lambda}{\mu_{1}} P \right) - \frac{\lambda}{\mu_{1}} P = T_{0}, \end{split}$$

which is a contradiction. Thus, (22) holds.

APPENDIX D

Assume that there exists a continuous optimal f_a^* such that (22) holds. By letting $\varpi \triangleq \frac{\tilde{h}^2 a^2}{\sigma^2}$ and based on Appendix A, we have

$$\omega(A; f_a^*) = -\int_0^{+\infty} \frac{2\bar{r}}{\sigma^2} \exp\left(-\frac{\bar{r}^2}{\sigma^2} - \varpi\right) \\ \times I_0\left(\frac{2\bar{r}\sqrt{\varpi}}{\sigma}\right) \log f_y(\bar{r}; f_a^*) d\bar{r} + \log(2\pi).$$
(34)

By using Laplace transform with respect to ϖ over (34), we have

$$\int_{0}^{+\infty} e^{-\varpi s} (\omega(A; f_a^*) - \log(2\pi)) d\varpi$$
$$= -\int_{0}^{+\infty} \int_{0}^{+\infty} \frac{2\bar{r}}{\sigma^2} \exp\left(-\frac{\bar{r}^2}{\sigma^2} - \varpi - \varpi s\right)$$
$$\times I_0\left(\frac{2\sqrt{\varpi}\bar{r}}{\sigma}\right) \log f_y(\bar{r}; f_a^*) d\bar{r} d\varpi.$$

By using [52, pp. 697]

$$\int_0^{+\infty} \exp(-\alpha x) I_0(2\sqrt{\beta x}) dx = \frac{1}{\alpha} \exp\left(\frac{\beta}{\alpha}\right),$$

we have

$$\int_{0}^{+\infty} e^{-\varpi s} (\omega(A; f_a^*) - \log(2\pi)) d\varpi$$
$$= -\int_{0}^{+\infty} \frac{2\bar{r}}{\sigma^2 (1+s)} \exp\left(-\frac{\bar{r}^2}{\sigma^2} \left(\frac{s}{1+s}\right)\right) \log f_y(\bar{r}; f_a^*) d\bar{r}$$
$$= -\frac{1}{\sigma^2 (1+s)} \int_{0}^{+\infty} \exp\left(-\frac{\xi}{\sigma^2} \left(\frac{s}{1+s}\right)\right) \log f_{\xi}(\xi; f_a^*) d\xi,$$

By using Laplace transform to the RHS of (22) with respect to ϖ , we have

$$\int_{0}^{+\infty} e^{-\varpi s} \left(T_0 - \left(\frac{\mu_2}{\mu_1} - 1\right) H(Y|\varpi) + \frac{\lambda \sigma^2 \varpi}{\mu_1 \tilde{h}^2} \right) d\varpi$$
$$= \frac{T_0}{s} + \frac{\lambda \sigma^2}{\mu_1 \tilde{h}^2 s^2} - \left(\frac{\mu_2}{\mu_1} - 1\right) \mathcal{H}(s),$$

where $\mathcal{H}(s) \triangleq \mathcal{L}(H(Y|\varpi))$. By letting $\beta = \frac{s}{\sigma^2(1+s)}$, the results of using Laplace transform and multiplied by s on both sides of (22) becomes

$$-\beta \int_{0}^{+\infty} \exp(-\xi\beta) \log f_{\xi}(\xi; f_{1}^{*}) d\xi$$
$$= T_{1} + \frac{\lambda(1-\beta\sigma^{2})}{\mu_{1}\tilde{h}^{2}\beta} - \left(\frac{\mu_{2}}{\mu_{1}} - 1\right) \frac{\beta\sigma^{2}}{1-\beta\sigma^{2}} \mathcal{H}\left(\frac{\beta\sigma^{2}}{1-\beta\sigma^{2}}\right), \quad (35)$$

where $T_1 = T_0 - \log(2\pi)$ Dividing (35) by β yields

$$\int_{0}^{+\infty} \exp\left(-\xi\beta\right) \log f_{\xi}(\xi; f_{1}^{*}) d\xi$$
$$= -\frac{T_{1}}{\beta} - \frac{\lambda(1-\beta\sigma^{2})}{\mu_{1}\tilde{h}^{2}\beta^{2}} + \left(\frac{\mu_{2}}{\mu_{1}} - 1\right) \frac{\sigma^{2}}{1-\beta\sigma^{2}} \mathcal{H}\left(\frac{\beta\sigma^{2}}{1-\beta\sigma^{2}}\right). \tag{36}$$

It is obvious that the left-hand side (LHS) of (36) is the unilateral Laplace transform of function $\log f(\xi; f_1^*)$, while the RHS of (36) can be recognized as the Laplace transform of

$$-T_1 + \frac{\lambda \sigma^2}{\mu_1 \tilde{h}^2} - \frac{\lambda \xi}{\mu_1 \tilde{h}^2} + \left(\frac{\mu_2}{\mu_1} - 1\right) \mathcal{L}^{-1} \left(\frac{\sigma^2}{1 - \beta \sigma^2} \mathcal{H} \left(\frac{\beta \sigma^2}{1 - \beta \sigma^2}\right); \xi\right)$$

which implies that

$$f_{\xi}(\xi; f_a^*) = \exp\left(-T_1 + \frac{\lambda\sigma^2}{\mu_1\tilde{h}^2} - \frac{\lambda\xi}{\mu_1\tilde{h}^2} + \left(\frac{\mu_2}{\mu_1} - 1\right)\mathcal{L}^{-1}\left(\frac{\sigma^2}{1 - \beta\sigma^2}\mathcal{H}\left(\frac{\beta\sigma^2}{1 - \beta\sigma^2}\right)\right); \xi\right).$$
(37)

From (37), one can find if $\mu_1 = \mu_2$, we have $f(\xi; f_a^*) = \exp\left(-T_1 + \frac{\lambda\sigma^2}{\mu_1\tilde{h}^2} - \frac{\lambda\xi}{\mu_1\tilde{h}^2}\right)$ such that the received signal Y follows a Gaussian distribution, which is achieved when X_1X_2 follows a Gaussian distribution. However, the points on boundary B-C require $\mu_2 > \mu_1$. Thus, we need to consider the effect of $\mathcal{L}^{-1}\left(\frac{\sigma^2}{1-\beta\sigma^2}\mathcal{H}(\frac{\beta\sigma^2}{1-\beta\sigma^2});\xi\right)$.

First, we focus on $\mathcal{H}(s)$. Based on (18), we have

$$\mathcal{H}(s) = \mathcal{L}(H(Y|\varpi)) = \mathcal{L}\left(\varpi(u(\varpi) - u(\varpi - 1))\right) \\ + \mathcal{L}\left(\frac{1}{2}\log\left(\frac{4\pi\varpi}{e}\right)u(\varpi - 1) + \log(\pi e \sigma^2)\right) \\ = \frac{1}{s^2} - \frac{e^{-s}}{s^2} - \frac{e^{-s}}{s} - \frac{1}{2s}\mathrm{Ei}(-s) + \log\left(\frac{4\pi}{e}\right)\frac{e^{-s}}{2s} + \frac{\log(\pi e \sigma^2)}{s},$$
(38)

where $u(\varpi)$ is a unit step function. Then, one of terms of $\mathcal{L}^{-1}\left(\frac{\sigma^2}{1-\beta\sigma^2}\mathcal{H}(\frac{\beta\sigma^2}{1-\beta\sigma^2});\xi\right)$ corresponds to the first term in (38), which is given by

$$\mathcal{L}^{-1}\left(\frac{1-\beta\sigma^2}{\beta^2\sigma^2};\xi\right) = \frac{\xi}{\sigma^2} - 1.$$

Due to $\frac{\mu_2}{\mu_1} - 1 > 0$, the PDF in (37) does not converge. Hence $f_{\xi}(\xi; f_1^*)$ in (37) cannot be a probability density. Thus, the increase points set E_0 of the optimal CDF F_a^* is finite, which implies that the optimal PDF f_a^* is discrete.

APPENDIX E

The distribution of X_1 is $f_1(X_1 = ae^{j\theta_1}) = \sum_{m=1}^{M} p_m \delta(a - a_m) \delta(\theta_1)$ and the distribution of X_2 is $f_2(X_2 = e^{j\theta_2}) = \frac{1}{2\pi}$. Based on Appendix A, we have

$$H(Y|X_1) = \int_{x_1} f_1(x_1) H(Y|X_1 = x_1) dx_1$$

= $-\sum_{m=1}^{M} p_m \int_0^{+\infty} \frac{2\bar{r}\bar{\kappa}(\bar{r}, a_m)}{\sigma^2} \log\left(\frac{2\bar{\kappa}(\bar{r}, a_m)}{\sigma^2}\right) d\bar{r} + \log(2\pi),$

where $\bar{\kappa}(\bar{r}, a_m) = \exp\left(-\frac{\bar{r}^2 + \bar{h}^2 a_m^2}{\sigma^2}\right) I_0\left(\frac{2\bar{r}\bar{h}a_m}{\sigma^2}\right)$. Then, $I(X_2; Y|X_1)$ is calculated by the definition of mutual information.

Next, we focus on the calculation of H(Y), which is given by $H(Y) = -\int_0^{+\infty} \int_{-\pi}^{\pi} f_y(\bar{r}, \bar{\psi}) \log(\frac{f_y(\bar{r}, \bar{\psi})}{\bar{r}}) d\bar{\psi} d\bar{r}$ and

$$\begin{split} f_y(\bar{r},\bar{\psi}) &= \bar{r} \int_{x_1} \int_{x_2} f_1(X_1) f_2(X_2) \\ &\quad \times \frac{1}{\pi \sigma^2} \exp\left(-\frac{|\bar{r}e^{j\psi} - \tilde{h}x_1x_2|^2}{\sigma^2}\right) dx_1 dx_2 \\ &= \sum_{m=1}^M \frac{p_m \bar{r}}{2\pi^2 \sigma^2} \int_{-\pi}^{\pi} \exp\left(-\frac{|\bar{r}e^{j\psi} - \tilde{h}a_m e^{j\theta_2}|^2}{\sigma^2}\right) d\theta_2 \\ &= \sum_{m=1}^M \frac{p_m \bar{r}}{2\pi^2 \sigma^2} \exp\left(-\frac{\bar{r}^2 + \tilde{h}^2 a_m^2}{\sigma^2}\right) \int_{-\pi}^{\pi} \\ &\quad \times \exp\left(\frac{2\bar{r}\tilde{h}a_m \cos(\theta_2 - \bar{\psi})}{\sigma^2}\right) d\theta_2 \\ &= \sum_{m=1}^M \frac{p_m \bar{r}}{\pi \sigma^2} \exp\left(-\frac{\bar{r}^2 + \tilde{h}^2 a_m^2}{\sigma^2}\right) I_0\left(\frac{2\bar{r}\tilde{h}a_m}{\sigma^2}\right). \end{split}$$

Since $f_y(\bar{r})$ satisfies $f_y(\bar{r}, \bar{\psi}) = \frac{1}{2\pi} f_y(\bar{r})$, we have $H(Y) = -\int_0^{+\infty} f_y(\bar{r}) \log \frac{f_y(\bar{r})}{\bar{r}} d\bar{r} + \log(2\pi)$. By the definition of mutual information, we can have $I(X_1; Y)$ and $I(X_2; Y|X_1)$.

APPENDIX F

Following the derivations of Appendix C, one can find that with constraint $|X_2| \leq 1$, (21) and (22) still hold. Similar to Appendix D, we assume that there exists a continuous optimal f_a^* such that (22) holds. Then, for the case $|X_2| \leq 1$, the marginal entropy $\omega(A; f_a^*)$ can be rewritten as

$$\omega(A; f_a^*) = -\int_0^{+\infty} f_r(r) \int_0^{+\infty} \frac{2\bar{r}}{\sigma^2} \exp\left(-\frac{\bar{r}^2}{\sigma^2} - r^2 \varpi\right) \\ \times I_0\left(\frac{2\bar{r}r\sqrt{\varpi}}{\sigma}\right) \log f_y(\bar{r}; f_a^*) d\bar{r} dr + \log(2\pi).$$
(39)

By using Laplace transform with respect to ϖ over (39), we have

$$\int_{0}^{+\infty} e^{-\varpi s} (\omega(A; f_{a}^{*}) - \log(2\pi)) d\varpi$$

$$= -\int_{0}^{+\infty} \frac{f_{r}(r)}{\sigma^{2}(r^{2} + s)} \int_{0}^{+\infty} \exp\left(-\frac{\xi}{\sigma^{2}}\left(\frac{s}{r^{2} + s}\right)\right) \log f_{\xi}(\xi; f_{a}^{*}) d\xi ds$$

$$= -\int_{0}^{+\infty} \frac{f_{r}(r)}{\sigma^{2}(r^{2} + s)} F\left(\frac{s}{(r^{2} + s)\sigma^{2}}\right) dr$$

$$= -\int_{0}^{+\infty} \frac{f_{r}(r)\beta(r, s)}{s} F\left(\beta(r, s)\right) dr$$

$$\stackrel{(a)}{=} \frac{T_{0} - \log(2\pi)}{s} + \frac{\lambda\sigma^{2}}{\mu_{1}\tilde{h}^{2}s^{2}} - \left(\frac{\mu_{2}}{\mu_{1}} - 1\right) \mathcal{H}(s), \quad (40)$$

where $F(s) = \mathcal{L}(\log f_{\xi}(\xi; f_a^*)), \ \beta(r, s) \triangleq \frac{s}{(r^2+s)\sigma^2}, \ \text{and} \ (a)$ holds by using Laplace transform to the RHS of (22). If there exists f_a^* such that (40) holds, there will exist $F_1(s), F_2(s)$, and $F_3(s)$ such that $\int_0^{+\infty} f_r(r)\beta(r,s)F_1(\beta(r,s)) dr = -T_0 + \log(2\pi), \ \int_0^{+\infty} f_r(r)\beta(r,s)F_2(\beta(r,s)) dr = -\frac{\lambda\sigma^2}{\mu_1\hbar^2s},$ and $\int_0^{+\infty} f_r(r)\beta(r,s)F_3(\beta(r,s)) dr = \left(\frac{\mu_2}{\mu_1} - 1\right)s\mathcal{H}(s),$ where $F(\beta(r,s)) = F_1(\beta(r,s)) + F_2(\beta(r,s)) + F_3(\beta(r,s)).$ It is straightforward to obtain $F_1(s) = \frac{-T_0 + \log(2\pi)}{\mu_1}$. As-

It is straightforward to obtain $F_1(s) = \frac{-10 + \log(2\pi)}{s}$. Assume that there exists a unique solution $F_2^*(s)$ such that $\int_0^{+\infty} f_r(r)\beta(r,s)F_2(\beta(r,s)) dr = -\frac{\lambda\sigma^2}{\mu_1\hbar^2s}$. To enable this equation, we have $F_2^*(\beta(r,s)) = \frac{-\lambda\sigma^4(r^2+s)}{\mu_1\hbar^2s^2}$, which yields $F_2^*(s) = \frac{-\lambda(1-s\sigma^2)}{\mu_1\hbar^2s^2r^2}$. If the amplitude of X_2 is constant, i.e., $|X_2| = r_0$, we have $F_2^*(s) = \frac{-\lambda(1-s\sigma^2)}{\mu_1\hbar^2s^2r_0^2}$, which is a unique solution and consistent with the results in Appendix D. In this case, the optimal f_a^* is discrete. If the amplitude of X_2 is related to r, which is not a unique solution. Thus, there is no solution for (40). This indicates that the amplitude of X_2 requires to be constant to enable X_1X_2 follows a Gaussian distribution, which coincides with the results in Section III-D.

In summary, there is no continuous optimal PDF f_a^* to enable (22) to hold. Hence, under constraint $|X_1| \leq 1$, the optimal PDF f_a^* is still discrete. For a discrete f_a^* , it is easy to have that f_r^* is also discrete by following the proof structures of Appendix C and Appendix D.
