# Multifractal analysis of the power-2-decaying Gauss-like expansion 

XUE-JIAO WANG ${ }^{\text {a,* }}$<br>${ }^{a}$ School of Mathematics and Statistics, Wuhan University, Wuhan 430072, China

#### Abstract

Each real number $x \in[0,1]$ admits a unique power-2-decaying Gauss-like expansion (P2GLE for short) as $x=\sum_{i \in \mathbb{N}} 2^{-\left(d_{1}(x)+d_{2}(x)+\cdots+d_{i}(x)\right)}$, where $d_{i}(x) \in \mathbb{N}$. For any $x \in(0,1]$, the Khintchine exponent $\gamma(x)$ is defined by $\gamma(x):=\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n} d_{j}(x)$ if the limit exists. We investigate the sizes of the level sets $E(\xi):=\{x \in(0,1]: \gamma(x)=\xi\}$ for $\xi \geq 1$. Utilizing the Ruelle operator theory, we obtain the Khintchine spectrum $\xi \mapsto \operatorname{dim}_{H} E(\xi)$, where $\operatorname{dim}_{H}$ denotes the Hausdorff dimension. We establish the remarkable fact that the Khintchine spectrum has exactly one inflection point, which was never proved for the corresponding spectrum in continued fractions. As a direct consequence, we also obtain the Lyapunov spectrum. Furthermore, we find the Hausdorff dimensions of the level sets $\left\{x \in(0,1]: \lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n} \log \left(d_{j}(x)\right)=\xi\right\}$ and $\left\{x \in(0,1]: \lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n} 2^{d_{j}(x)}=\xi\right\}$.

## 1. Introduction and main results

Let $\mathbb{N}=\{1,2, \ldots\}$ denote the set of positive integers. The power-2-decaying Gauss-like expansion (P2GLE for short) of a real number can be generated by the transformation $T:(0,1] \rightarrow(0,1]$ defined by

$$
\begin{equation*}
T x:=2^{n} x-1 \quad \text { for } x \in\left(1 / 2^{n}, 1 / 2^{n-1}\right], \quad n \in \mathbb{N} . \tag{1.1}
\end{equation*}
$$

By [8, Proposition 2.1], we know that every real number $x$ in $(0,1]$ can be written uniquely as the form

$$
\begin{equation*}
x=\sum_{i=1}^{\infty} 2^{-\left(d_{1}(x)+d_{2}(x)+\cdots+d_{i}(x)\right)} \tag{1.2}
\end{equation*}
$$

where $d_{1}(x)=\left\lceil-\log _{2} x\right\rceil$ and $d_{i}(x)=d_{1}\left(T^{i-1} x\right)$ for $i \geq 2$. Here, we use $\lceil x\rceil$ to denote the smallest integer greater than or equal to $x$. For any $d_{1}, \cdots, d_{n} \in \mathbb{N}$, the $n$ th-order cylinder is defined by

$$
I_{n}\left(d_{1}, \cdots, d_{n}\right):=\left\{x \in(0,1]: d_{1}(x)=d_{1}, \cdots, d_{n}(x)=d_{n}\right\}
$$

Let $\varphi:[0,1] \rightarrow \mathbb{R}$ be a real-valued function (usually called potential). For any $n \geq 1$, denote the $n$th Birkhoff sum of $\varphi$ by

$$
S_{n} \varphi(x):=\sum_{j=0}^{n-1} \varphi\left(T^{j} x\right), \quad x \in[0,1]
$$

[^0]The Birkhoff average of $\varphi$ is defined as

$$
\bar{\varphi}(x):=\lim _{n \rightarrow \infty} \frac{1}{n} S_{n} \varphi(x), \quad x \in(0,1]
$$

(if the limit exists). In multifractal analysis, we are interested in the Hausdorff dimension of the level sets

$$
\begin{equation*}
E_{\varphi}(\xi)=\{x \in(0,1]: \bar{\varphi}(x)=\xi\}, \quad \xi \in \mathbb{R} \tag{1.3}
\end{equation*}
$$

The so-called Birkhoff spectrum is the function $t_{\varphi}: \mathbb{R} \rightarrow[0,1] \cup\{-\infty\}$ defined by

$$
t_{\varphi}(\xi):=\operatorname{dim}_{H} E_{\varphi}(\xi)
$$

where $\operatorname{dim}_{H} E_{\varphi}(\xi)$ denotes the Hausdorff dimension of $E_{\varphi}(\xi)$. By convention, $\operatorname{dim}_{H} \emptyset=0$.
Some metric theorems of P2GLE have been obtained in [7-9]. In particular, in [9] we know that the transformation $T$ is measure-preserving and ergodic with respect to the Lebesgue measure. In [8], the author showed that the Hausdorff dimension of the set of numbers with prescribed digits in $A \subset \mathbb{N}$ in their P2GLE is the unique real solution of $\sum_{n \in A} 2^{-n s}=1$, and hence the set

$$
\left\{x \in(0,1]: d_{i}(x) \text { is bounded }\right\}
$$

has Hausdorff dimension one. It is known to [7] that

$$
\operatorname{dim}_{H}\left\{x \in(0,1]: \lim _{i \rightarrow \infty} d_{i}(x)=\infty\right\}=0
$$

In this paper, we aim at finding the Birkhoff spectrum $\xi \mapsto \operatorname{dim}_{H} E_{\varphi}(\xi)$ for different choices of potential $\varphi$ for P2GLE. For any $x \in(0,1]$ with P2GLE (1.2), we define its Khintchine exponent $\gamma(x)$ and Lyapunov exponent $\lambda(x)$ respectively by

$$
\begin{aligned}
& \gamma(x):=\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n} d_{j}(x)=\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=0}^{n-1} d_{1}\left(T^{j} x\right) \\
& \lambda(x):=\lim _{n \rightarrow \infty} \frac{1}{n} \log \left|\left(T^{n}\right)^{\prime}(x)\right|=\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=0}^{n-1} \log \left|T^{\prime}\left(T^{j} x\right)\right|
\end{aligned}
$$

if the limits exist. By definition, the Khintchine exponent is the Birkhoff average of the potential $x \mapsto d_{1}(x)$, and the Lyapunov exponent is the Birkhoff average of the potential $x \mapsto \log \left|T^{\prime}(x)\right|$.

Since the transformation $T$ is ergodic with respect to the Lebesgue measure, it follows that for Lebesgue almost all $x$ in $(0,1]$,

$$
\begin{aligned}
& \gamma(x)=\int\left\lceil-\log _{2} x\right\rceil \mathrm{d} x=\sum_{n=1}^{\infty} n 2^{-n}=2 \\
& \lambda(x)=\int \log \left|T^{\prime}(x)\right| \mathrm{d} x=(\log 2) \sum_{n=1}^{\infty} n 2^{-n}=2 \log 2
\end{aligned}
$$

Note that $\gamma(x) \geq 1$ and $\lambda(x) \geq \log 2$ for all $x$ in $(0,1]$. We study the level sets:

$$
E(\xi):=\{x \in(0,1]: \gamma(x)=\xi\}, \quad \xi \geq 1
$$

and

$$
F(\beta):=\{x \in(0,1]: \lambda(x)=\beta\}, \quad \beta \geq \log 2
$$

The Khintchine spectrum and Lyapunov spectrum are defined by

$$
\begin{aligned}
t(\xi) & :=\operatorname{dim}_{H} E(\xi), \quad \xi \geq 1 \\
\tilde{t}(\beta): & =\operatorname{dim}_{H} F(\beta), \quad \beta \geq \log 2
\end{aligned}
$$

Fan, Liao, Wang and Wu ([2]) obtained complete graphs of the Khintchine spectrum and Lyapunov spectrum of the Gauss map associated to continued fractions. Applying the method of [2], we study the Birkhoff spectra of P2GLE. The major tool is the Ruelle operator theory. For a given potential $\varphi$, we define the pressure function by

$$
\begin{equation*}
P(t, q)=P_{\varphi}(t, q):=\lim _{n \rightarrow \infty} \frac{1}{n} \log \sum_{\omega_{1} \in \mathbb{N}} \sum_{\omega_{2} \in \mathbb{N}} \cdots \sum_{\omega_{n} \in \mathbb{N}} \exp \left(\sup _{\substack{d_{i}(x)=\omega_{i} \\ 1 \leq i \leq n}} S_{n}\left(-t \log \left|T^{\prime}(x)\right|+q \varphi(x)\right)\right) \tag{1.4}
\end{equation*}
$$

We will prove (Theorem 3.1) that $\operatorname{dim}_{H} E_{\varphi}(\xi)$ is exactly the first coordinate $t(\xi)$ of the unique solution $(t(\xi), q(\xi))$ of the system

$$
\left\{\begin{array}{l}
P(t, q)=q \xi  \tag{1.5}\\
\frac{\partial P}{\partial q}(t, q)=\xi
\end{array}\right.
$$

The notation $P_{\varphi}(t, q)$ and $E_{\varphi}(\xi)$ will be consistently used through this paper, and their specific forms are determined by the potential $\varphi$.

We obtain the following results of Khintchine spectrum for P2GLE.
Theorem 1.1. We have $\operatorname{dim}_{H} E(1)=0$ and for any $\xi>1$,

$$
\begin{equation*}
t(\xi)=\operatorname{dim}_{H} E(\xi)=\frac{\frac{\log (\xi-1)}{\xi}+\log \xi-\log (\xi-1)}{\log 2} \tag{1.6}
\end{equation*}
$$

Furthermore, the Khintchine spectrum $t: \xi \mapsto \operatorname{dim}_{H} E(\xi)$ has the following properties:
(1) $t(2)=1$;
(2) $\lim _{\xi \rightarrow 1} t(\xi)=0$ and $\lim _{\xi \rightarrow \infty} t(\xi)=0$;
(3) $t^{\prime}(\xi)>0$ for $\xi<2, t^{\prime}(2)=0$, and $t^{\prime}(\xi)<0$ for $\xi>2$;
(4) $\lim _{\xi \rightarrow 1} t^{\prime}(\xi)=\infty$ and $\lim _{\xi \rightarrow \infty} t^{\prime}(\xi)=0$;
(5) the function $t(\xi)$ has exactly one inflection point.

Figure 1: Khintchine spectrum $\left(\varphi(x)=d_{1}(x)\right)$

We remark that the last point of Theorem 1.1 was not proved for continued fraction expansion in [2]. The reason is that in our P2GLE case, we have an explicit formula for the pressure function $P(t, q)$, while in the continued fraction expansion case such formula does not exist.

The Lyapunov spectrum gains in interest if we realize that

$$
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=0}^{n-1} \log \left|T^{\prime}\left(T^{j} x\right)\right|=(\log 2) \cdot \lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n} d_{j}(x)
$$

Therefore, replacing $\xi$ by $\frac{\beta}{\log 2}$ in (1.6), we obtain the Lyapunov spectrum.
Corollary 1.1. We have $\operatorname{dim}_{H} F(\log 2)=0$ and for any $\beta>\log 2$,

$$
\begin{equation*}
\tilde{t}(\beta)=\operatorname{dim}_{H} F(\beta)=\frac{1}{\beta} \log \left(\frac{\beta}{\log 2}-1\right)-\frac{1}{\log 2} \log \left(1-\frac{\log 2}{\beta}\right) \tag{1.7}
\end{equation*}
$$

Furthermore, the Lyapunov spectrum $\tilde{t}: \beta \mapsto \tilde{t}(\beta)$ has the following properties:
(1) $\tilde{t}(2 \log 2)=1$;
(2) $\lim _{\beta \rightarrow \log 2} \tilde{t}(\beta)=0$ and $\lim _{\beta \rightarrow \infty} \tilde{t}(\beta)=0$;
(3) $\tilde{t}^{\prime}(\beta)>0$ for $\beta<2 \log 2, \tilde{t}^{\prime}(2 \log 2)=0$, and $\tilde{t}^{\prime}(\beta)<0$ for $\beta>2 \log 2$;
(4) $\lim _{\beta \rightarrow \log 2} \tilde{t}^{\prime}(\beta)=\infty$ and $\lim _{\beta \rightarrow \infty} \tilde{t}^{\prime}(\beta)=0$;
(5) the function $\tilde{t}(\beta)$ has exactly one inflection point.

We illustrate the Birkhoff spectra in Theorem 1.1 and Corollary 1.1 by Figures 1 and 2.
The same method also works for general potential $\varphi$. To illustrate some different Birkhoff spectra, we study the special cases of $\varphi(x)=\log \left(d_{1}(x)\right)$ and $\varphi(x)=2^{d_{1}(x)}$. From the Birkhoff ergodic theorem, we deduce that for Lebesgue almost all $x$ in $(0,1]$,

$$
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=0}^{n-1} \log \left(d_{1}\left(T^{j} x\right)\right)=\xi_{0}=\int \log \left\lceil-\log _{2} x\right\rceil \mathrm{d} x=\sum_{n=1}^{\infty} 2^{-n} \log n \approx 0.507834
$$

Figure 2: Lyapunov spectrum $\left(\varphi(x)=\log \left|T^{\prime}(x)\right|\right)$
and

$$
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=0}^{n-1} 2^{d_{1}\left(T^{j} x\right)}=\int 2^{\left\lceil-\log _{2} x\right\rceil} \mathrm{d} x=\infty
$$

Now let us state our main results for $\varphi(x)=\log \left(d_{1}(x)\right)$ and $\varphi(x)=2^{d_{1}(x)}$.
Theorem 1.2. Let $\varphi:(0,1] \rightarrow \mathbb{R}$ be the potential defined by $\varphi(x)=\log \left(d_{1}(x)\right)$, with $d_{1}(x)=\left\lceil-\log _{2} x\right\rceil$, and $E_{\varphi}(\xi)$ be defined as in (1.3). Then, we have that the pressure function $P$ defined in (1.4) is

$$
P(t, q)=P_{\varphi}(t, q)=\log \left(\sum_{n=1}^{\infty} 2^{-n t} \cdot n^{q}\right)
$$

and that for any $\xi>0$, there exists a unique solution $(t(\xi), q(\xi))$ to the system (1.5). Moreover, $\operatorname{dim}_{H} E_{\varphi}(0)=$ 0 and for any $\xi>0, \operatorname{dim}_{H} E_{\varphi}(\xi)=t(\xi)$. Let $\xi_{0}=\int_{0}^{1} \log \left\lceil-\log _{2} x\right\rceil \mathrm{d} x$. The Birkhoff spectrum $t: \xi \mapsto t(\xi)$ has the following properties:
(1) $t\left(\xi_{0}\right)=1$;
(2) $t^{\prime}(\xi)>0$ for $\xi<\xi_{0}, t^{\prime}\left(\xi_{0}\right)=0$, and $t^{\prime}(\xi)<0$ for $\xi>\xi_{0}$;
(3) $\lim _{\xi \rightarrow 0} t(\xi)=0$ and $\lim _{\xi \rightarrow \infty} t(\xi)=0$;
(4) $\lim _{\xi \rightarrow 0} t^{\prime}(\xi)=\infty$;
(5) $t^{\prime \prime}\left(\xi_{0}\right)<0$ and there exits $\xi_{1}>\xi_{0}$ such that $t^{\prime \prime}\left(\xi_{1}\right)>0$, so the function $t(\xi)$ is neither convex nor concave.

Theorem 1.3. Let $\varphi(x)=2^{d_{1}(x)}$ for $x \in(0,1]$. Then the pressure function $P$ defined in (1.4) is

$$
P(t, q)=P_{\varphi}(t, q)=\log \left(\sum_{n=1}^{\infty} 2^{-n t} e^{2^{n} q}\right)
$$

We have that $\operatorname{dim}_{H} E_{\varphi}(2)=0$ and for any $\xi>2, \operatorname{dim}_{H} E_{\varphi}(\xi)=t(\xi)$, which is the first coordinate of the unique solution of the equation (1.5). The Birkhoff spectrum $t: \xi \mapsto t(\xi)$ has the following properties:
(1) $\operatorname{dim}_{H} E_{\varphi}(\infty)=1$;
(2) $t^{\prime}(\xi)>0$ for $\xi>2$;
(3) $\lim _{\xi \rightarrow 2} t(\xi)=0$ and $\lim _{\xi \rightarrow \infty} t(\xi)=1$;
(4) $\lim _{\xi \rightarrow 2} t^{\prime}(\xi)=\infty$ and $\lim _{\xi \rightarrow \infty} t^{\prime}(\xi)=0$;

An outline of this paper is as follows. In Section 2, we review the Ruelle operator theory and the method of pressure function. In Sections 3 and 4, we prove the results for Khintchine and Lyapunov spectra (Theorem 1.1 and Corollary 1.1). Sections 5 and 6 are devoted to proving Theorems 1.2 and 1.3 respectively.

## 2. Conformal iterated function systems and Ruelle operator theory

### 2.1. Conformal iterated function systems

From now on, $X$ stands for a non-empty compact connected subset of $\mathbb{R}^{d}$ equipped with a metric $\rho$. Let $S=\left\{\phi_{i}: X \rightarrow X: i \in \mathbb{N}\right\}$ be an iterated function system for which there exists $0<s<1$ such that for each $i \in \mathbb{N}$ and all $x, y \in X$,

$$
\begin{equation*}
\rho\left(\phi_{i}(x), \phi_{i}(y)\right) \leq s \rho(x, y) \tag{2.1}
\end{equation*}
$$

We follow the notation of [2].

- $\mathbb{N}^{n}:=\left\{\omega: \omega=\left(\omega_{1}, \cdots \omega_{n}\right), \omega_{k} \in \mathbb{N}, 1 \leq k \leq n\right\}$.
- $\mathbb{N}^{\infty}:=\prod_{i=1}^{\infty} \mathbb{N}$.
- $\left[\left.\omega\right|_{n}\right]=\left[\omega_{1} \cdots \omega_{n}\right]=\left\{x \in \mathbb{N}^{\infty}: x_{1}=\omega_{1}, \cdots x_{n}=\omega_{n}\right\}$.
- $|\omega|$ denotes the length of $\omega$.
- $\phi_{\omega}=\phi_{\omega_{1}} \circ \phi_{\omega_{2}} \cdots \phi_{\omega_{n}}$ for $\omega=\left(\omega_{1}, \cdots \omega_{n}\right) \in \mathbb{N}^{n}, n \geq 1$.
- $\left\|\phi_{\omega}^{\prime}\right\|:=\sup _{x \in X}\left|\phi_{\omega}^{\prime}(x)\right|$ for $\omega \in \bigcup_{n \geq 1} \mathbb{N}^{n}$.
- $C(X)$ denotes the space of continuous functions on $X$.
- $\sigma: \mathbb{N}^{\infty} \rightarrow \mathbb{N}^{\infty}$ is the shift tramsformation.
- $\|\cdot\|_{\infty}$ denotes the supremum norm on $C(X)$.

Let $\partial X$ denote the boundary of $X$ and $\operatorname{Int} X$ denote the interior of $X$. Our definitions agree with the classical one for conformal iterated function system. For details, see [5] and [2].

An iterated function system $S=\left\{\phi_{i}\right\}_{i \in \mathbb{N}}$ (IFS for short) is said to be conformal if the following conditions are satisfied:
(1) The open set condition is satisfied for $\operatorname{Int}(X)$, i.e., $\phi_{i}(\operatorname{Int} X) \subset \operatorname{Int}(X)$ for each $i \in \mathbb{N}$ and $\phi_{i}(\operatorname{Int} X) \bigcap \phi_{j}(\operatorname{Int} X)=\emptyset$ for each $(i, j) \in \mathbb{N}^{2}, i \neq j$.
(2) There exists an open connected set $V$ with $X \subset V \subset \mathbb{R}^{d}$ such that all maps $\phi_{i}, i \in \mathbb{N}$, extend to $C^{1}$ conformal diffemorphisms of $V$ into $V$.
(3) There exist $h, l>0$ such that for each $x \in \partial X \subset \mathbb{R}^{d}$, there exists an open cone $\operatorname{Con}(x, h, l) \subset \operatorname{Int} X$ with vertex $x$, central angle of Lebesgue measure $h$ and altitude $l$.
(4) There exists $K \geq 1$ such that $\left|\phi_{\omega}^{\prime}(y)\right| \leq K\left|\phi_{\omega}^{\prime}(x)\right|$ for every $\omega \in \cup_{n \geq 1} \mathbb{N}^{n}$ and every pair of points $x, y \in V$ (Bounded distortion property).

The topological pressure function for the conformal iterated function system $S=\left\{\phi_{i}: X \rightarrow X: i \in\right.$ $\mathbb{N}\}$ is defined as

$$
\begin{equation*}
P(t)=\lim _{n \rightarrow \infty} \frac{1}{n} \log \sum_{\omega \in \mathbb{N}^{n}}\left\|\phi_{\omega}^{\prime}\right\|^{t} . \tag{2.2}
\end{equation*}
$$

The system $S$ is said to be regular if there exists $t \geq 0$ such that $P(t)=0$.
Let $X=[0,1]$. The P2GLE dynamical system is associated with an IFS:

$$
S=\left\{\phi_{i}(x)=2^{-i}(x+1): i \in \mathbb{N}\right\}
$$

In fact, the functions $\phi_{i}$ are inverse branches of the transformation $T$ defined in (1.1). The coding map $\pi: N^{\infty} \rightarrow X$ is defined by

$$
\pi(\omega)=\bigcap_{n=1}^{\infty} \phi_{\left.\omega\right|_{n}}(X)=\sum_{n=1}^{\infty} 2^{-\left(\omega_{1}+\omega_{2}+\cdots \omega_{n}\right)} \quad \text { for any } \omega=\left(\omega_{1}, \omega_{2} \cdots\right)
$$

Notice that for each $i \in \mathbb{N}$ and for all $x, y \in[0,1]$,

$$
\left|\phi_{i}(x)-\phi_{i}(y)\right| \leq \frac{1}{2}|x-y|
$$

Lemma 2.1. The IFS S associated to P2GLE is conformal.
Proof. (1) The open set condition is satisfied for $\operatorname{Int} X=(0,1)$, since

$$
\phi_{i}(\operatorname{Int} X)=\left(2^{-i}, 2^{-i+1}\right) \subset \operatorname{Int} X \quad \text { for each } i \in \mathbb{N},
$$

and

$$
\phi_{i}(\operatorname{Int} X) \bigcap \phi_{j}(\operatorname{Int} X)=\emptyset \quad \text { for each }(i, j) \in \mathbb{N}^{2}, i \neq j
$$

(2) Let $V=(-1,2)$. It follows that $X \subset V$ and all maps $\phi_{i}, i \in \mathbb{N}$, extend to $C^{1}$ conformal diffemorphisms of $V$ into $V$.
(3) The third condition of conformal IFS was proved by [4, Section 2].
(4) The bounded distortion property holds, since $\left|\phi_{\omega}^{\prime}(y)\right|=\left|\phi_{\omega}^{\prime}(x)\right|=2^{-\left(\omega_{1}+\omega_{2}+\cdots+\omega_{n}\right)}$ for every $\omega \in$ $\mathbb{N}^{n}, n \geq 1$ and every pair of points $x, y \in V$.

Lemma 2.2. The iterated function system $S$ is regular.
Proof. Observe that

$$
\left\|\phi_{\omega}^{\prime}\right\|=\sup _{x \in X}\left|\phi_{\omega}^{\prime}(x)\right|=2^{-\left(\omega_{1}+\omega_{2}+\cdots+\omega_{n}\right)} .
$$

By definition, the topological pressure function for $S$ is

$$
\begin{aligned}
P(t) & =\lim _{n \rightarrow \infty} \frac{1}{n} \log \sum_{\omega \in \mathbb{N}^{n}}\left\|\phi_{\omega}^{\prime}\right\|^{t} \\
& =\lim _{n \rightarrow \infty} \frac{1}{n} \log \sum_{\omega_{1} \in \mathbb{N}} \sum_{\omega_{2} \in \mathbb{N}} \cdots \sum_{\omega_{n} \in \mathbb{N}} 2^{-t\left(\omega_{1}+\omega_{2}+\cdots+\omega_{n}\right)} \\
& =-\log \left(2^{t}-1\right)
\end{aligned}
$$

It is easily seen that $P(1)=0$. Hence, $S$ is regular.

### 2.2. Ruelle operator theory

Let $\beta>0$. A Hölder family of functions of order $\beta$ is a family of continuous functions

$$
G=\left\{g^{(i)}: X \rightarrow \mathbb{R}\right\}_{i \in \mathbb{N}}
$$

such that

$$
V_{\beta}(G)=\sup _{n \geq 1} V_{n}(G)<\infty,
$$

where

$$
V_{n}(G)=\sup _{\omega \in \mathbb{N}^{n}} \sup _{x, y \in X}\left\{\left|g^{\left(\omega_{1}\right)}\left(\phi_{\sigma(\omega)}(x)\right)-g^{\left(\omega_{1}\right)}\left(\phi_{\sigma(\omega)}(y)\right)\right|\right\} e^{\beta(n-1)} .
$$

A Hölder family of functions $G=\left\{g^{(i)}: X \rightarrow \mathbb{R}\right\}_{i \in \mathbb{N}}$ is said to be strong if

$$
\begin{equation*}
\sum_{i \in \mathbb{N}}\left\|e^{g^{(i)}}\right\|_{\infty}<\infty \tag{2.3}
\end{equation*}
$$

The Ruelle operator on $C(X)$ associated with $G$ is defined by

$$
\mathcal{L}_{G}(h)(x):=\sum_{i \in \mathbb{N}} e^{g^{(i)}} h\left(\phi_{i}(x)\right), \quad \forall h \in C(X) .
$$

Denote by $\mathcal{L}_{G}^{*}$ the dual of $\mathcal{L}_{G}$.
The topological pressure of $G$ is defined by

$$
\begin{equation*}
P(G):=\lim _{n \rightarrow \infty} \frac{1}{n} \log \sum_{|\omega|=n} \exp \left(\sup _{x \in X} \sum_{j=1}^{n} g^{\left(\omega_{j}\right)} \circ \phi_{\sigma^{j} \omega}(x)\right) . \tag{2.4}
\end{equation*}
$$

Let $S=\left\{\phi_{i}: X \rightarrow X\right\}_{i \in \mathbb{N}}$ be a conformal iterated function system, $\Psi=\left\{\psi_{i}: X \rightarrow \mathbb{R}, i \in \mathbb{N}\right\}$, and $F=\left\{f_{i}: X \rightarrow \mathbb{R}, i \in \mathbb{N}\right\}$ be two families of real-valued Hölder functions. The amalgamated functions on $\mathbb{N}^{\infty}$ associated with $\Psi$ and $F$ are defined as

$$
\tilde{\psi}(\omega)=\psi_{\omega_{1}}(\pi(\sigma \omega)), \quad \tilde{f}(\omega)=f_{\omega_{1}}(\pi(\sigma \omega)) .
$$

The following theorems will be useful.
Theorem 2.1. ([3, Theorem 6.4]) Let $\Psi=\left\{\psi_{i}\right\}_{i \in \mathbb{N}}$ and $F=\left\{f_{i}\right\}_{i \in \mathbb{N}}$ be two Hölder families of functions. Suppose the sets $\left\{i \in \mathbb{N}: \sup _{x}\left(\psi_{i}(x)\right)>0\right\}$ and $\left\{i \in \mathbb{N}: \sup _{x}\left(f_{i}(x)\right)>0\right\}$ are finite. Then the function $(t, q) \mapsto P(t, q)=P(t \Psi-q F)$ is real analytic with respect to $(t, q) \in \operatorname{Int}(D)$, where

$$
D=\left\{(t, q): \sum_{i \in \mathbb{N}} \exp \left(\sup _{x}\left(t \psi_{i}(x)-q f_{i}(x)\right)\right)<\infty\right\} .
$$

Theorem 2.2. ([3, Section 2]) Suppose that $t \Psi-q F$ is a strong Hölder family for any $(t, q) \in D$. For each $(t, q) \in D$, there exists a unique $(t \Psi-q F)$-conformal probability measure $\nu_{t, q}$ on $X$ such that $\mathcal{L}_{t \Psi-q F}^{*} \nu_{t, q}=e^{P(t, q)} \nu_{t, q}$, and a unique shift invariant ergodic probability measure $\tilde{\mu}_{t, q}$ on $\mathbb{N}^{\infty}$ such that the measure $\mu_{t, q}:=\tilde{\mu}_{t, q} \circ \pi^{-1}$ on $X$ is equivalent to $\nu_{t, q}$ and the Gibbs property is satisfied:

$$
\frac{1}{C} \leq \frac{\tilde{\mu}_{t, q}\left(\left[\left.\omega\right|_{n}\right]\right)}{\exp \left(\sum_{j=1}^{n}(t \Psi-q F)^{\left(\omega_{j}\right)}\left(\pi\left(\sigma^{j} \omega\right)\right)-n P(t, q)\right)} \leq C \quad \text { for all } \omega \in \mathbb{N}^{\infty}
$$

Theorem 2.3. ([3]) If $t \Psi-q F$ is a strong Hölder family for any $(t, q) \in D$ and

$$
\int(|\tilde{\psi}|+|\tilde{f}|) \mathrm{d} \tilde{\mu}_{t, q}<\infty
$$

then

$$
\begin{equation*}
\frac{\partial P}{\partial t}=\int \tilde{\psi} \mathrm{d} \tilde{\mu}_{t, q} \quad \text { and } \quad \frac{\partial P}{\partial q}=-\int \tilde{f} \mathrm{~d} \tilde{\mu}_{t, q} \tag{2.5}
\end{equation*}
$$

Ift $\tilde{\psi}-q \tilde{f}$ is not cohomologous to a constant with respect to the transformation $T$, i.e., there is no function $u \in C(X)$ such that

$$
t \tilde{\psi}-q \tilde{f}=u-u \circ T+C
$$

where $C$ is a constant, then $P(t, q)$ is strictly convex and the matrix

$$
H(t, q):=\left[\begin{array}{cc}
\frac{\partial^{2} p}{\partial t^{2}} & \frac{\partial^{2} p}{\partial t \partial q} \\
\frac{\partial^{2} p}{\partial t \partial q} & \frac{\partial^{2} p}{\partial q^{2}}
\end{array}\right]
$$

is positive definite.
Consider the level sets

$$
E_{\varphi}(\xi)=\{x \in(0,1]: \bar{\varphi}(x)=\xi\}, \quad \xi \in \mathbb{R}
$$

Let $P(t, q)$ be the corresponding pressure function of the potential $t \Psi-q F$ and $D$ be the analytic area of $P(t, q)$. By [2, Lemma 4.7], we know that if $\tilde{\psi}(\omega)=-\log \left|T^{\prime}(\pi(\omega))\right|$ and $\tilde{f}(\omega)=-\varphi(\pi(\omega))$. Then

$$
\begin{equation*}
-\int \log \left|T^{\prime}(x)\right| \mathrm{d} \mu_{t, q}=\int \tilde{\psi} \mathrm{d} \tilde{\mu}_{t, q} \quad \text { and } \quad \int \varphi(x) \mathrm{d} \mu_{t, q}=-\int \tilde{f} \mathrm{~d} \tilde{\mu}_{t, q} \tag{2.6}
\end{equation*}
$$

and $t \tilde{\psi}-q \tilde{f}$ is not cohomologous to a constant.
Applying Theorem 2.3, we arrive at the following proposition.
Proposition 2.1. ([2, Proposition 4.8]) The following statements hold on $D$.
(1) $P(t, q)$ is analytic and strictly convex.
(2) $P(t, q)$ is strictly decreasing and strictly convex with respect to $t$, i.e., $(\partial p / \partial t)(t, q)<0$ and $\left(\partial^{2} p / \partial t^{2}\right)(t, q)>$ 0 . Furthermore,

$$
\begin{equation*}
\frac{\partial p}{\partial t}(t, q)=-\int \log \left|T^{\prime}(x)\right| \mathrm{d} \mu_{t, q} . \tag{2.7}
\end{equation*}
$$

(3) $P(t, q)$ is strictly increasing and strictly convex with respect to $q$, i.e., $(\partial p / \partial q)(t, q)>0$ and $\left(\partial^{2} p / \partial q^{2}\right)(t, q)>$ 0. Furthermore,

$$
\begin{equation*}
\frac{\partial p}{\partial q}(t, q)=\int \varphi(x) \mathrm{d} \mu_{t, q} \tag{2.8}
\end{equation*}
$$

(4) The matrix

$$
H(t, q):=\left[\begin{array}{cc}
\frac{\partial^{2} p}{\partial t^{2}} & \frac{\partial^{2} p}{\partial t \partial q} \\
\frac{\partial^{2} p}{\partial t \partial q} & \frac{\partial^{2} p}{\partial q^{2}}
\end{array}\right]
$$

is positive definite.

## 3. Khintchine spectrum

Recall that the transformation $T$ on $X=(0,1]$ associated to P2GLE is defined as

$$
T x=2^{n} x-1 \quad \text { for } x \in\left(1 / 2^{n}, 1 / 2^{n-1}\right], \quad n \in \mathbb{N}
$$

and the corresponding conformal iterated function system on $X$ is

$$
S=\left\{\phi_{i}(x)=2^{-i}(x+1): i \in \mathbb{N}\right\}
$$

Now we will calculate the Hausdorff dimensions of the level sets
$E(\xi)=\left\{x \in(0,1]: \lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n} d_{j}(x)=\xi\right\}=\left\{x \in(0,1]: \lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=0}^{n-1}\left\lceil-\log _{2}\left(T^{j}(x)\right)\right\rceil=\xi\right\}, \quad \xi \geq 1$.
Let $\Psi=\left\{\log \left|\phi_{i}^{\prime}\right|: i \in \mathbb{N}\right\}=\{-i \log 2: i \in \mathbb{N}\}$ and $F=\{-i: i \in \mathbb{N}\}$. It can be checked that $\Psi$ and $F$ are two families of real-valued Hölder functions.

Proposition 3.1. Let $D:=\{(t, q): q-t \log 2<0\}$. For any $(t, q) \in D$, we have
(1) the family $t \Psi-q F$ is Hölder and strong;
(2) the topological pressure $P$ of the potential $t \Psi-q F$ is

$$
\begin{equation*}
P(t, q)=\log \frac{e^{-t \log 2+q}}{1-e^{-t \log 2+q}} \tag{3.1}
\end{equation*}
$$

Proof. (1) We first show that the family $t \Psi-q F$ is Hölder. Since

$$
(t \Psi-q F)^{(i)}:=t \log \left|\phi_{i}^{\prime}\right|+q i=i(-t \log 2+q)
$$

we have $V_{n}(t \Psi-q F)=0$. By definition, $t \Psi-q F$ is Hölder.
For $(t, q) \in D$, replacing $g^{(i)}$ by $i(-t \log 2+q)$ in (2.3), we obtain that

$$
\sum_{i \in \mathbb{N}}\left\|e^{i(-t \log 2+q)}\right\|_{\infty}<\infty
$$

Thus $t \Psi-q F$ is strong.
(2) It suffices to notice that $(t \Psi-q F)^{(i)}$ is a constant function for each $i \in \mathbb{N}$. Thus

$$
\sup _{x \in X} \sum_{j=1}^{n}(t \Psi-q F)^{\left(\omega_{j}\right)} \circ \phi_{\sigma^{j} \omega}(x)=(-t \log 2+q) \sum_{j=1}^{n} \omega_{j}
$$

By definition,

$$
\begin{aligned}
P(t, q) & =\lim _{n \rightarrow \infty} \frac{1}{n} \log \sum_{\omega_{1}, \omega_{2} \cdots \omega_{n} \in \mathbb{N}} \exp \left((-t \log 2+q) \sum_{j=1}^{n} \omega_{j}\right) \\
& =\lim _{n \rightarrow \infty} \frac{1}{n} \log \left(\frac{e^{-t \log 2+q}}{1-e^{-t \log 2+q}}\right)^{n} \\
& =\log \frac{e^{-t \log 2+q}}{1-e^{-t \log 2+q}} .
\end{aligned}
$$

### 3.1. Proof of (1.6) in Theorem 1.1

Let us find the solution of the system (1.5).
Proposition 3.2. For any $\xi \in(1, \infty)$, the unique solution of the system

$$
\left\{\begin{array}{l}
P(t, q)=q \xi  \tag{3.2}\\
\frac{\partial P}{\partial q}(t, q)=\xi
\end{array}\right.
$$

is

$$
\left\{\begin{aligned}
t(\xi) & =\frac{\frac{\log (\xi-1)}{\xi}+\log \xi-\log (\xi-1)}{\log 2} \\
q(\xi) & =\frac{\log (\xi-1)}{\xi}
\end{aligned}\right.
$$

Proof. Since

$$
\begin{equation*}
P(t, q)=\log \frac{e^{-t \log 2+q}}{1-e^{-t \log 2+q}} \tag{3.3}
\end{equation*}
$$

we have

$$
\begin{equation*}
\frac{\partial P}{\partial q}(t, q)=\frac{1}{1-e^{-t \log 2+q}} \tag{3.4}
\end{equation*}
$$

Substituting (3.3) and (3.4) into the above system yields

$$
e^{-t \log 2+q}=\frac{e^{q \xi}}{1+e^{q \xi}}=\frac{\xi-1}{\xi}
$$

Hence, $q(\xi)=\frac{\log (\xi-1)}{\xi}$ and $t(\xi)=\frac{\frac{\log (\xi-1)}{\xi}+\log \xi-\log (\xi-1)}{\log 2}$.

Lemma 3.1. For any $\xi>1$, let $(t(\xi), q(\xi))$ be the solution of (3.2). Then the measure $\mu_{t(\xi), q(\xi)}$ obtained by Theorem 2.2 is supported on $E(\xi)$, i.e., $\mu_{t(\xi), q(\xi)}(E(\xi))>0$.

Proof. By (2.8),

$$
\int\left\lceil-\log _{2} x\right\rceil \mathrm{d} \mu_{t, q}=\frac{\partial P}{\partial q}(t, q)
$$

Take $(t, q)=(t(\xi), q(\xi))$. By the ergodicity of $\mu_{t(\xi), q(\xi)}$ and the second equation in (3.2), we have that for $\mu_{t(\xi), q(\xi)}$-almost every $x$,

$$
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=0}^{n-1}\left\lceil-\log _{2}\left(T^{j}(x)\right)\right\rceil=\int\left\lceil-\log _{2} x\right\rceil \mathrm{d} \mu_{t(\xi), q(\xi)}=\frac{\partial P}{\partial q}(t(\xi), q(\xi))=\xi
$$

Therefore, $\mu_{t(\xi), q(\xi)}(E(\xi))=1>0$.

The following lemma is a consequence of Theorem 2.2. We use the notation $f \asymp g$ to mean that $\frac{1}{C} f(x) \leq g(x) \leq C f(x)$ for some constant $C>0$ and for all $x \in X$.

Lemma 3.2. For $x \in X$, let $I_{n}(x):=\left\{y \in X: d_{i}(y)=d_{i}(x), 1 \leq i \leq n\right\}$ and $\omega=\pi^{-1}(x)$. Then

$$
\begin{equation*}
\mu_{t, q}\left(I_{n}(x)\right) \asymp \exp \left(\sum_{j=1}^{n}(t \Psi-q F)^{\left(\omega_{j}\right)}\left(\pi\left(\sigma^{j} \omega\right)\right)-n P(t, q)\right) \tag{3.5}
\end{equation*}
$$

Proof. Notice that $\mu_{t, q}\left(I_{n}(x)\right)=\tilde{\mu}_{t, q}\left(\left[\left.\omega\right|_{n}\right]\right)$. Then $\mu_{t, q}$ is a Gibbs measure on $X$, i.e., there exists $C>0$, such that

$$
\frac{1}{C} \leq \frac{\mu_{t, q}\left(I_{n}(x)\right)}{\exp \left(\sum_{j=1}^{n}(t \Psi-q F)^{\left(\omega_{j}\right)}\left(\pi\left(\sigma^{j} \omega\right)\right)-n P(t, q)\right)} \leq C
$$

Theorem 3.1. For any $\xi>1$, we have

$$
\begin{equation*}
\operatorname{dim}_{H} E(\xi)=t(\xi)=\frac{\frac{\log (\xi-1)}{\xi}+\log \xi-\log (\xi-1)}{\log 2} \tag{3.6}
\end{equation*}
$$

Proof. Let $(t, q) \in D$. Since

$$
(t \Psi-q F)^{(i)}=i(-t \log 2+q)
$$

we have

$$
\exp \left(\sum_{j=1}^{n}(t \Psi-q F)^{\left(\omega_{j}\right)}\left(\pi\left(\sigma^{j} \omega\right)\right)-n P(t, q)\right)=\exp \left((-t \log 2+q) \sum_{j=1}^{n} \omega_{j}-n P(t, q)\right)
$$

By Lemma 3.5,

$$
\begin{equation*}
\mu_{t, q}\left(I_{n}(x)\right) \asymp \exp \left((-t \log 2+q) \sum_{j=1}^{n} d_{j}-n P(t, q)\right) \tag{3.7}
\end{equation*}
$$

Fix $\xi>1$. For any $x \in E(\xi)$, we have

$$
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n} d_{j}(x)=\xi
$$

Observe that

$$
\left|I_{n}(x)\right|=2^{-d_{1}(x)+d_{2}(x)+\cdots d_{n}(x)}
$$

Take $(t, q)=(t(\xi), q(\xi))$. Then $P(t, q)=q \xi$, and

$$
\begin{aligned}
d_{\mu}(x) & =\liminf _{n \rightarrow \infty} \frac{\log \mu_{t, q}\left(I_{n}(x)\right)}{\log \left|I_{n}(x)\right|} \\
& =\liminf _{n \rightarrow \infty} \frac{(-t \log 2+q) \sum_{j=1}^{n} d_{j}-n P(t, q)}{-\left(\sum_{j=1}^{n} d_{j}\right) \log 2} \\
& =\frac{-t \xi \log 2+q \xi-q \xi}{-\xi \log 2} \\
& =t
\end{aligned}
$$

By Billingsley's lemma (see [1, Lemma 1.4.1]), for $\xi>1$, we have $\operatorname{dim}_{H} E(\xi)=t(\xi)$.

Summarizing, we have proved that the unique solution $t(\xi)$ of (3.2) is the Khintchine spectrum for $\xi>1$. Now let us discuss the properties of the function $\xi \mapsto t(\xi)$.

### 3.2. Proofs of Theorem 1.1 (1)-(4)

Recall that the level set

$$
E(2)=\{x \in(0,1]: \gamma(x)=2\}
$$

has Lebesgue measure one. This implies $\operatorname{dim}_{H} E(2)=1$.
By Theorem 3.1,

$$
\operatorname{dim}_{H} E(\xi)=t(\xi)=\frac{\frac{\log (\xi-1)}{\xi}+\log \xi-\log (\xi-1)}{\log 2}, \quad \text { for all } \xi>1
$$

Letting $\xi \rightarrow 1$ and $\xi \rightarrow \infty$ respectively, we have

$$
\lim _{\xi \rightarrow 1} t(\xi)=0, \quad \lim _{\xi \rightarrow \infty} t(\xi)=0
$$

This is assertion (2) of Theorem 1.1.
By differentiating the equation in (3.6) with respect to $\xi$, we arrive at the following proposition.
Proposition 3.3. For $\xi>1$,

$$
\begin{equation*}
t^{\prime}(\xi)=\frac{\log (\xi-1)}{-\xi^{2} \log 2} \tag{3.8}
\end{equation*}
$$

By (3.8), we see immediately that $t^{\prime}(\xi)>0$ for $\xi<2, t^{\prime}(2)=0$, and $t^{\prime}(\xi)<0$ for $\xi>2$. Furthermore,

$$
\lim _{\xi \rightarrow 1} t^{\prime}(\xi)=\infty, \quad \lim _{\xi \rightarrow \infty} t^{\prime}(\xi)=0
$$

We are now in a position to show the boundary case of Theorem 1.1.
Proposition 3.4. $\operatorname{For} \xi=1, \operatorname{dim}_{H} E(1)=0$.
Proof. It is sufficient to show that

$$
\begin{equation*}
\operatorname{dim}_{H} E(1) \leq t \log 2, \quad \text { for all } t>0 \tag{3.9}
\end{equation*}
$$

For any $t>0$, from $\lim _{\xi \rightarrow 1} t(\xi)=0$ and $q(\xi)=\frac{\log (\xi-1)}{\xi}$, it follows that there exists $\xi>1$ such that $0<t(\xi)<t$ and $q(\xi)<0$. Since $P(t, q)$ is strictly decreasing with respect to $t$, we can choose $\varepsilon_{0}>0$ such that

$$
\frac{P(t, q(\xi))-P(t(\xi), q(\xi))}{q(\xi)}>\varepsilon_{0}
$$

For $n \geq 1$, set

$$
E_{0}^{n}\left(\varepsilon_{0}\right):=\left\{x \in[0,1): \frac{1}{n} \sum_{j=1}^{n} d_{j}(x)<\frac{1}{\log 2}\left(\xi+\varepsilon_{0}\right)\right\}
$$

Since $\frac{1}{\log 2}\left(\xi+\varepsilon_{0}\right)>1$,

$$
E(1) \subset \bigcup_{N=1}^{\infty} \bigcap_{n=N}^{\infty} E_{0}^{n}\left(\varepsilon_{0}\right)
$$

Let $\mathcal{I}\left(n, \xi, \varepsilon_{0}\right)$ denote the family of all $n$ th-order cylinders $I_{n}\left(d_{1}, \cdots, d_{n}\right)$ such that

$$
\frac{1}{n} \sum_{j=1}^{n} d_{j}(x)<\frac{1}{\log 2}\left(\xi+\varepsilon_{0}\right)
$$

Then

$$
E_{0}^{n}\left(\varepsilon_{0}\right)=\bigcup_{J \in \mathcal{I}\left(n, \xi, \varepsilon_{0}\right)} J
$$

Hence, $\left\{J: J \in \mathcal{I}\left(n, \xi, \varepsilon_{0}\right), n \geq 1\right\}$ is a cover of $E(1)$. It remains to prove that

$$
\sum_{n=1}^{\infty} \sum_{J \in \mathcal{I}\left(n, \xi, \varepsilon_{0}\right)}|J|^{t \log 2}<\infty
$$

By (3.7) and the fact that $\left|I_{n}(x)\right|=2^{-\left(d_{1}(x)+\cdots+d_{n}(x)\right)}$, we have

$$
\mu_{t, q}\left(I_{n}(x)\right) \asymp \exp (-n P(t, q)) 2^{q \sum_{j=1}^{n} d_{j}}\left|I_{n}(x)\right|^{t \log 2}
$$

Thus,

$$
\begin{align*}
& \sum_{n=1}^{\infty} \sum_{J \in \mathcal{I}\left(n, \xi, \varepsilon_{0}\right)}|J|^{t \log 2}=\sum_{n=1}^{\infty} \sum_{\sum_{j=1}^{n} d_{j}<\left(\xi+\varepsilon_{0}\right) n \log _{2} e \frac{e^{n P(t, q(\xi))}}{2^{q(\xi) \sum_{j=1}^{\infty} d_{j}}} \frac{|J|^{t \log 2} 2^{q(\xi) \sum_{j=1}^{\infty} d_{j}}}{e^{n P(t, q(\xi))}}}  \tag{3.10}\\
& \leq C \sum_{n=1}^{\infty} e^{n P(t, q(\xi))-\left(\xi+\varepsilon_{0}\right) q(\xi)} \cdot \sum_{J \in \mathcal{I}\left(n, \xi, \varepsilon_{0}\right)} \mu_{t, q(\xi)}(J)<\infty, \tag{3.11}
\end{align*}
$$

where $C$ is a constant. Hence, we obtain (3.9).

### 3.3. Proof of Theorem 1.1 (5)

The following proposition proves the last assertion of Theorem 1.1, i.e., $t(\xi)$ has only one inflection point.

Proposition 3.5. We have

$$
\begin{equation*}
t^{\prime \prime}(\xi)=\frac{2(\xi-1) \log (\xi-1)-\xi}{\xi^{3}(\xi-1) \log 2}, \quad \forall \xi>1 \tag{3.12}
\end{equation*}
$$

Further, there exists a point $\tilde{\xi}$ such that $t^{\prime \prime}(\tilde{\xi})=0$ and $t^{\prime \prime}(\xi)<0$ for $\xi<\tilde{\xi}, t^{\prime \prime}(\xi)>0$ for $\xi>\tilde{\xi}$.
Proof. For $\xi>1$, we have $\xi^{3}(\xi-1) \log 2>0$. Define a function $f$ by $f(\xi)=2(\xi-1) \log (\xi-1)-\xi$ for all $\xi>1$. Notice that

$$
\lim _{\xi \rightarrow 1} f(\xi)=-1<0, \quad \lim _{\xi \rightarrow \infty} f(\xi)=\infty
$$

Taking the derivative of $f$ gives $f^{\prime}(\xi)=2 \log (\xi-1)+1$. We then deduce that $f$ is strictly decreasing on $\left(1,1+e^{-1 / 2}\right)$ and increasing on $\left(1+e^{-1 / 2}, \infty\right)$. Observe that $f(3)<0$, and $f(1+e)>0$. Therefore, there exists exactly one point $\tilde{\xi} \in(3,1+e)$ such that $t^{\prime \prime}(\tilde{\xi})=0$. The rest of the statements are evident.

## 4. Birkhoff spectrum for $\varphi: x \mapsto \log \left(d_{1}(x)\right)$

Let $\varphi(x)=\log \left(d_{1}(x)\right)=\log \left(\left\lceil-\log _{2} x\right\rceil\right)$. We consider the Hausdorff dimensions of the sets

$$
E_{\varphi}(\xi)=\left\{x \in(0,1]: \lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=0}^{n-1} \log \left(d_{1}\left(T^{j} x\right)\right)=\xi\right\}, \quad \xi \geq 0
$$

Recall that, for Lebesgue almost all $x$ in $(0,1]$,

$$
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=0}^{n-1} \log \left(d_{1}\left(T^{j} x\right)\right)=\xi_{0}=\int_{0}^{1} \log \left\lceil-\log _{2} x\right\rceil \mathrm{d} x
$$

Thus $\operatorname{dim}_{H} E_{\varphi}\left(\xi_{0}\right)=1$.
Let $\Psi=\left\{\log \left|\phi_{i}^{\prime}\right|: i \in \mathbb{N}\right\}=\{-i \log 2: i \in \mathbb{N}\}$ and $F=\{-\log i: i \in \mathbb{N}\}$.
Proposition 4.1. Let $D:=\{(t, q): t>0$, or $t=0, q<-1\}$. For any $(t, q) \in D$ :
(1) the family $t \Psi-q F$ is Hölder and strong;
(2) the topological pressure $P(t, q)$ of the potential $t \Psi-q F$ is given by

$$
\begin{equation*}
P(t, q)=\log \left(\sum_{n=1}^{\infty} 2^{-n t} \cdot n^{q}\right) . \tag{4.1}
\end{equation*}
$$

Proof. (1) Since $(t \Psi-q F)^{(i)}=-t i \log 2+q \log i$, we have $V_{n}(t \Psi-q F)=0$. By definition, the family $t \Psi-q F$ is Hölder.

For $(t, q) \in D$, it can be checked that

$$
\sum_{i \in \mathbb{N}} e^{-t i \log 2+q \log i}<\infty
$$

Thus $t \Psi-q F$ is strong.
(2) Observe that

$$
\sup _{x \in X} \sum_{j=1}^{n}(t \Psi-q F)^{\left(\omega_{j}\right)} \circ \phi_{\sigma^{j} \omega}(x)=-t \log 2 \sum_{j=1}^{n} \omega_{j}+q \sum_{j=1}^{n} \log \omega_{j} .
$$

By definition,

$$
\begin{aligned}
P(t, q) & =\lim _{n \rightarrow \infty} \frac{1}{n} \log \sum_{\omega_{1}, \omega_{2} \cdots \omega_{n} \in \mathbb{N}} \exp \left(-t(\log 2) \sum_{j=1}^{n} \omega_{j}+q \sum_{j=1}^{n} \log \omega_{j}\right) \\
& =\lim _{n \rightarrow \infty} \frac{1}{n} \log \left(\sum_{\omega=1}^{\infty} \exp (-t \omega \log 2+q \log \omega)\right)^{n} \\
& =\log \left(\sum_{n=1}^{\infty} 2^{-n t} \cdot n^{q}\right) .
\end{aligned}
$$

By Theorem 2.1 and Proposition 4.1, we know that $D$ is the analytic area of the pressure $P(t, q)$. From Mayer [6] (see also Pollicott and Weiss [10, Proposition 4]), we know that $\mu_{1,0}$ is the Lebesgue measure on $[0,1]$. By (2.8), we obtain

$$
\begin{equation*}
\frac{\partial P}{\partial q}(1,0)=\int \log \left\lceil-\log _{2} x\right\rceil \mathrm{d} x=\xi_{0} \tag{4.2}
\end{equation*}
$$

### 4.1. Further sutdy on $P(t, q)$

Now we show some properties of $P(t, q)$ and $\partial P / \partial q$.
Proposition 4.2. For fixed $t>0$,

$$
\begin{equation*}
\frac{\partial P}{\partial q}(t, q)=\frac{\sum_{n=1}^{\infty} 2^{-n t}(\log n) n^{q}}{\sum_{n=1}^{\infty} 2^{-n t} n^{q}}, \quad \forall q \in \mathbb{R} \tag{4.3}
\end{equation*}
$$

Moreover, we have

$$
\begin{equation*}
P(t, 0)=-\log \left(2^{t}-1\right) \tag{4.4}
\end{equation*}
$$

and

$$
\begin{equation*}
P(0, q)=\log \zeta(-q), \tag{4.5}
\end{equation*}
$$

where $\zeta$ is the Riemann zeta function, defined by

$$
\zeta(s):=\sum_{n=1}^{\infty} \frac{1}{n^{s}}, \quad \forall s>1
$$

Consequently:
(1) $P(1,0)=0$, and

$$
\lim _{q \rightarrow-\infty} P(0, q)=0 ;
$$

(2) for fixed $t>0$,

$$
\lim _{q \rightarrow \infty} P(t, q)=\infty
$$

(3) for fixed $t \geq 0$,

$$
\begin{equation*}
\lim _{q \rightarrow-\infty} \frac{\partial P}{\partial q}(t, q)=0 \tag{4.6}
\end{equation*}
$$

(4) we have

$$
\begin{equation*}
\lim _{t \rightarrow 0} \frac{\partial P}{\partial q}(t, 0)=\infty \tag{4.7}
\end{equation*}
$$

Proof. Fix $t>0$ and $q_{0}>0$. Notice that for any $n \in \mathbb{N}$ and $q \leq q_{0}$,

$$
2^{-n t}(\log n) n^{q} \leq 2^{-n t}(\log n) n^{q_{0}}
$$

Since the series $\sum_{n=1}^{\infty} 2^{-n t}(\log n) n^{q_{0}}$ is convergent, we arrive at (4.3). Since

$$
P(t, 0)=\log \left(\sum_{n=1}^{\infty} 2^{-n t}\right)=-\log \left(2^{t}-1\right)
$$

we have $P(1,0)=0$. Notice that

$$
P(0, q)=\log \left(\sum_{n=1}^{\infty} n^{q}\right)=\log \zeta(-q)
$$

and

$$
\lim _{q \rightarrow-\infty} \zeta(-q)=1
$$

Then, we have $P(0, q) \rightarrow 0(q \rightarrow-\infty)$. We have thus proved (4.4), (4.5) and part (1).
Next, let $q \rightarrow \infty$. We note that $n^{q} \rightarrow \infty$ for all $n>1$, hence $P(t, q) \rightarrow \infty$. This proves part (2).
Now, let $q \rightarrow-\infty$. Since $n^{q} \rightarrow 0$, we have

$$
\lim _{q \rightarrow-\infty} \frac{\partial P}{\partial q}(t, q)=\lim _{q \rightarrow-\infty} \frac{\sum_{n=1}^{\infty} 2^{-n t}(\log n) n^{q}}{2^{-t}+\sum_{n=2}^{\infty} 2^{-n t} n^{q}}=0
$$

which is the assertion of part (3).
For the final part, let $q=0$. By (4.3), we have

$$
\frac{\partial P}{\partial q}(t, 0)=\frac{\sum_{n=1}^{\infty} 2^{-n t}(\log n)}{\sum_{n=1}^{\infty} 2^{-n t}}
$$

Fix $M>0$. Then there extsts $N \in \mathbb{N}$, such that $\log n>M$ for any $n \geq N$. Hence,

$$
\frac{\partial P}{\partial q}(t, 0)>\frac{(\log 2) \sum_{n=2}^{k-1} 2^{-n t}+M \sum_{n=k}^{\infty} 2^{-n t}}{\sum_{n=1}^{\infty} 2^{-n t}}=2^{-2 t}(\log 2)\left(1-2^{-(k-2) t}\right)+M 2^{-k t}
$$

Notice that

$$
\lim _{t \rightarrow 0} 2^{-2 t}(\log 2)\left(1-2^{-(k-2) t}\right)+M 2^{-k t}=M
$$

Thus,

$$
\lim _{t \rightarrow 0} \frac{\partial P}{\partial q}(t, 0) \geq M
$$

Hence, letting $M \rightarrow \infty$, we obtain (4.7).
Recall that $\xi_{0}=(\partial P / \partial q)(1,0)$. Let $\tilde{D}=\{(t, q) \in D: 0 \leq t \leq 1\}$.
Proposition 4.3 ([2]). For any $\xi \in(0, \infty)$, the system

$$
\left\{\begin{array}{l}
P(t, q)=q \xi  \tag{4.8}\\
\frac{\partial P}{\partial q}(t, q)=\xi
\end{array}\right.
$$

admits a unique solution $(t(\xi), q(\xi)) \in \tilde{D}$. For $\xi=\xi_{0}$, the unique solution is $\left(t\left(\xi_{0}\right), q\left(\xi_{0}\right)\right)=(1,0)$. Further, the functions $t(\xi)$ and $q(\xi)$ are analytic.

By differentiating the first equation in system (4.8) with respect to $\xi$ and applying the second equation in (4.8), we obtain the first derivative of function $t$ with respect to $\xi$, i.e.,

$$
\begin{equation*}
t^{\prime}(\xi)=\frac{q(\xi)}{(\partial P / \partial t)(t(\xi), q(\xi))}, \quad \forall \xi>0 \tag{4.9}
\end{equation*}
$$

### 4.2. Proof of Theorem 1.2

As is widely known, if $f$ is a convex continuously differentiable function on an interval $I$, then $f^{\prime}$ is increasing and

$$
f^{\prime}(x) \leq \frac{f(y)-f(x)}{y-x} \leq f^{\prime}(y) \quad \forall x, y \in I, x<y
$$

Using this fact, we next present some properties on $t(\xi)$.
The proof of the following proposition is similar to that of [2, Proposition 4.14].
Proposition 4.4. $q(\xi)<0$ for $\xi<\xi_{0} ; q\left(\xi_{0}\right)=0 ; q(\xi)>0$ for $\xi>\xi_{0}$.
Proof. By the convexity of the function $P(1, q)$ with respect to $q$, and the fact $P(1,0)=0$, we have

$$
\frac{P(1, q)-0}{q-0} \geq \frac{\partial P}{\partial q}(1,0)=\xi_{0} \quad(q>0) ; \quad \frac{0-P(1, q)}{0-q} \leq \frac{\partial P}{\partial q}(1,0)=\xi_{0} \quad(q<0)
$$

Thus

$$
P(1, q) \geq \xi_{0} q, \quad \forall q \in \mathbb{R}
$$

Proposition 4.3 shows that $t(\xi)=1$ if and only if $\xi=\xi_{0}$. Suppose $t \in(0,1)$. For $\xi>\xi_{0}$, if $q(\xi) \leq 0$, then

$$
P(t, q)>P(1,0) \geq q \xi_{0} \geq q \xi
$$

which contradicts to the first equation in (4.8). Thus

$$
q(\xi)>0 \quad\left(\xi>\xi_{0}\right)
$$

The rest of the proof runs as before.

Let us use Proposition 4.4 and (4.9) to deduce some further properties of $t(\xi)$.
Proposition 4.5. We have $t^{\prime}(\xi)>0$ for $\xi<\xi_{0}, t^{\prime}\left(\xi_{0}\right)=0$, and $t^{\prime}(\xi)<0$ for $\xi>\xi_{0}$. Furthermore,

$$
\begin{array}{ll}
t(\xi) \rightarrow 0 & (\xi \rightarrow 0) \\
t(\xi) \rightarrow 0 & (\xi \rightarrow \infty) \tag{4.11}
\end{array}
$$

Proof. By Proposition 2.1(2), $\partial P / \partial t<0$. Hence, according to Proposition 4.4 and (4.9), $t(\xi)$ is strictly increasing on $\left(0, \xi_{0}\right)$ and decreasing on $\left(\xi_{0}, \infty\right)$. Then by the analyticity of $t(\xi)$, we can obtain two analytic inverse functions on the two intervals respectively. For the first inverse function, write $\xi_{1}=\xi_{1}(t)$. Then $\xi_{1} \in\left(0, \xi_{0}\right)$ and $\xi_{1}^{\prime}(t)>0$. Considering equations (4.8) as equations on $t$, we have

$$
\xi_{1}(t)=\frac{P(t, q(t))}{q(t)}=\frac{\partial P}{\partial q}(t, q(t))
$$

Since $\xi_{1}(t) \in\left(0, \xi_{0}\right)$, we conclude that $q\left(\xi_{1}(t)\right)<0$, and in consequence, $P\left(t, q\left(\xi_{1}(t)\right)\right)<0$. By Proposition 4.2(2), $\lim _{q \rightarrow \infty} P(t, q)=\infty$. Thus there exits $q_{0}(t)$ such that $q_{0}(t)>q(t)$ and $P\left(t, q_{0}(t)\right)=0$. From $\partial^{2} p / \partial q^{2}>0$, we see that

$$
\xi_{1}(t)=\frac{\partial P}{\partial q}(t, q(t))<\frac{\partial P}{\partial q}\left(t, q_{0}(t)\right)
$$

Since $P(0, q)=\log \zeta(-q)$, then $\lim _{t \rightarrow 0} q_{0}(t)=-\infty$. Consequently,

$$
\lim _{t \rightarrow 0} \frac{\partial P}{\partial q}\left(t, q_{0}(t)\right)=\lim _{q \rightarrow-\infty} \frac{\partial P}{\partial q}(0, q)=0
$$

From the above, it follows that $\lim _{t \rightarrow 0} \xi_{1}(t)=0$, and so $\lim _{\xi \rightarrow 0} t(\xi)=0$.
For the second inverse function, write $\xi_{2}=\xi_{2}(t)$. Then $\xi_{2} \in\left(\xi_{0}, \infty\right)$ and $\xi_{2}^{\prime}(t)<0$. An analysis similar to that in the proof of the first inverse function shows that

$$
\xi_{2}(t)=\frac{\partial P}{\partial q}(t, q(t))>\frac{\partial P}{\partial q}(t, 0) .
$$

From (4.7), we deduce that $\lim _{\xi \rightarrow \infty} t(\xi)=0$.
As in the proof of [2, Proposition 5.1 ], we obtain the following proposition.
Proposition 4.6. We have

$$
\begin{equation*}
\lim _{\xi \rightarrow 0} q(\xi)=-\infty \tag{4.12}
\end{equation*}
$$

Proposition 4.7. We have the following two properties of $\partial P / \partial t$.
(1) For $t>0$,

$$
\lim _{q \rightarrow-\infty} \frac{\partial P}{\partial t}(t, q)=-\log 2 .
$$

(2) For $q=0$,

$$
\lim _{t \rightarrow 0} \frac{\partial P}{\partial t}(t, 0)=-\infty
$$

Proof. For $t>0$ and $q<-2$,

$$
\begin{equation*}
\frac{\partial P}{\partial t}(t, q)=\frac{(-\log 2) \sum_{n=1}^{\infty} 2^{-n t} n^{q+1}}{\sum_{n=1}^{\infty} 2^{-n t} n^{q}} \tag{4.13}
\end{equation*}
$$

Therefore,

$$
\lim _{q \rightarrow-\infty} \frac{\partial P}{\partial t}(t, q)=-\log 2 .
$$

For $q=0, P(t, 0)=-\log \left(2^{t}-1\right)$. Therefore,

$$
\frac{\partial P}{\partial t}(t, 0)=\frac{-2^{t} \log 2}{2^{t}-1}, \quad \lim _{t \rightarrow 0} \frac{\partial P}{\partial t}(t, 0)=-\infty .
$$

Combining Propositions 4.6 and 4.7 yields

$$
\lim _{\xi \rightarrow 0} t^{\prime}(\xi)=\infty
$$

We have thus proved (1)-(4) of Theorem 1.2.
Our next goal is to calculate the value of $\operatorname{dim}_{H} E_{\varphi}(0)$.

Theorem 4.1. $\operatorname{For} \xi=0, \operatorname{dim}_{H} E_{\varphi}(0)=0$.
Proof. For any $t>0$, since $\lim _{\xi \rightarrow 0} t(\xi)=0$, there exists $0<\xi<\xi_{0}$ such that $0<t(\xi)<t$ and $q(\xi)<0$. Then we can choose $\varepsilon_{0}>0$, such that

$$
\frac{P(t, q(\xi))-P(t(\xi), q(\xi))}{q(\xi)}>\varepsilon_{0} .
$$

Let $\mathcal{I}\left(n, \xi, \varepsilon_{0}\right)$ be the family of all $n$ th-order cylinders $I_{n}\left(d_{1}, \cdots, d_{n}\right)$ such that

$$
\frac{1}{n} \sum_{j=1}^{n} \log \left(d_{j}(x)\right)<\xi+\varepsilon_{0} .
$$

Then $\left\{J: J \in \mathcal{I}\left(n, \xi, \varepsilon_{0}\right), n \geq 1\right\}$ is a cover of $E_{\varphi}(0)$. Since $(t \Psi-q F)^{(i)}=-t i \log 2+q \log i$, by Lemma 3.5,

$$
\mu_{t, q}\left(I_{n}(x)\right) \asymp \exp (-n P(t, q))\left|I_{n}(x)\right|^{t}\left(d_{1} \cdots d_{n}\right)^{q} .
$$

A calculation similar to that in the proof of Proposition 3.4 shows that

$$
\begin{align*}
\sum_{n=1}^{\infty} \sum_{J \in \mathcal{I}\left(n, \xi, \varepsilon_{0}\right)}|J|^{t} & =\sum_{n=1}^{\infty} \sum_{\left(d_{1} \cdots d_{n}\right)<e^{n\left(\xi+\varepsilon_{0}\right)}} \frac{e^{n P(t, q(\xi))}}{\left(d_{1} \cdots d_{n}\right)^{q(\xi)}} \frac{|J|^{t}\left(d_{1} \cdots d_{n}\right)^{q(\xi)}}{e^{n P(t, q(\xi))}}  \tag{4.14}\\
& \leq C \sum_{n=1}^{\infty} e^{n P(t, q(\xi))-\left(\xi+\varepsilon_{0}\right) q(\xi)} \cdot \sum_{J \in \mathcal{I}\left(n, \xi, \varepsilon_{0}\right)} \mu_{t, q(\xi)}(J)<\infty \tag{4.15}
\end{align*}
$$

Thus $\operatorname{dim}_{H} E_{\varphi}(0) \leq t$. By the arbitrariness of $t, \operatorname{dim}_{H} E_{\varphi}(0)=0$.
For a rigorous proof of the last assertion of Theorem 1.2, we refer the reader to [2, p.103]. A point that should be stressed is that the number of inflection points is not clear yet.

## 5. Birkhoff spectrum for $\varphi: x \mapsto 2^{d_{1}(x)}$

Consider the level sets

$$
E_{\varphi}(\xi)=\left\{x \in(0,1]: \lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=0}^{n-1} 2^{d_{1}\left(T^{j} x\right)}=\xi\right\}, \quad \xi \geq 2
$$

with $\varphi(x)=2^{d_{1}(x)}$.
Let $\Psi=\left\{\log \left|\phi_{i}^{\prime}\right|: i \in \mathbb{N}\right\}=\{-i \log 2: i \in \mathbb{N}\}$ and $F=\left\{-2^{i}: i \in \mathbb{N}\right\}$. It can be checked that $\Psi$ and $F$ are two families of real-valued Hölder functions.

Proposition 5.1. Let $D:=\{(t, q): t>0, q=0$ or $q<0\}$. For $(t, q) \in D$ :
(1) the family $t \Psi-q F$ is Hölder and strong;
(2) the topological pressure $P$ of the potential $t \Psi-q F$ is

$$
\begin{equation*}
P(t, q)=\log \left(\sum_{n=1}^{\infty} 2^{-n t} e^{2^{n} q}\right) . \tag{5.1}
\end{equation*}
$$

Proof. (1) Since $(t \Psi-q F)^{(i)}=-t i \log 2+q 2^{i}, V_{n}(t \Psi-q F)=0$. By definition, $t \Psi-q F$ is Hölder.
For $(t, q) \in D$, we have

$$
\sum_{i \in \mathbb{N}} e^{-t i \log 2+q 2^{i}}=\sum_{i \in \mathbb{N}} 2^{-i t} e^{2^{i} q}<\infty
$$

Thus $t \Psi-q F$ is strong.
(2) Observe that

$$
\sup _{x \in X} \sum_{j=1}^{n}(t \Psi-q F)^{\left(\omega_{j}\right)} \circ \phi_{\sigma^{j} \omega}(x)=-t \log 2 \sum_{j=1}^{n} \omega_{j}+q \sum_{j=1}^{n} 2^{\omega_{j}}
$$

By definition,

$$
\begin{aligned}
P(t, q) & =\lim _{n \rightarrow \infty} \frac{1}{n} \log \sum_{\omega_{1}, \omega_{2} \cdots \omega_{n} \in \mathbb{N}} \exp \left(-t \log 2 \sum_{j=1}^{n} \omega_{j}+q \sum_{j=1}^{n} 2^{\omega_{j}}\right) \\
& =\lim _{n \rightarrow \infty} \frac{1}{n} \log \left(\sum_{\omega=1}^{\infty} 2^{-\omega t} e^{2^{\omega} q}\right)^{n} \\
& =\log \left(\sum_{n=1}^{\infty} 2^{-n t} e^{2^{n} q}\right)
\end{aligned}
$$

Let us investigate some properties of $P(t, q)$. Let $D_{1}=\{(t, q): t \geq 0, q<0\}$.
Proposition 5.2. $\operatorname{For}(t, q) \in D_{1}$,

$$
\begin{equation*}
\frac{\partial P}{\partial q}(t, q)=\frac{\sum_{n=1}^{\infty} 2^{-n(t-1)} e^{2^{n} q}}{\sum_{n=1}^{\infty} 2^{-n t} e^{2^{2} q}} \tag{5.2}
\end{equation*}
$$

Consequently,
(1) for fixed $0<t \leq 1$,

$$
\begin{equation*}
\lim _{q \rightarrow 0} \frac{\partial P}{\partial q}(t, q)=\infty \tag{5.3}
\end{equation*}
$$

(2) we have

$$
\begin{equation*}
\lim _{(t, q) \rightarrow(0,0)} \frac{\partial P}{\partial q}(t, q)=\infty \tag{5.4}
\end{equation*}
$$

(3) for fixed $t \geq 0$ and $q<0$, we have $(\partial P / \partial q)(t, q)>2$, and

$$
\begin{equation*}
\lim _{q \rightarrow-\infty} \frac{\partial P}{\partial q}(t, q)=2 \tag{5.5}
\end{equation*}
$$

Proof. Fix $t \geq 0$ and $q_{0}<0$. Then for any $q \leq q_{0}$, we have

$$
2^{-n(t-1)} e^{2^{n} q} \leq 2^{-n(t-1)} e^{2^{n} q_{0}}
$$

Notice that

$$
\lim _{n \rightarrow \infty} \sqrt[n]{2^{-n(t-1)} e^{2^{n} q_{0}}}=0<1
$$

By Weierstrass M-test, we have that the series $\sum_{n=1}^{\infty} 2^{-n(t-1)} e^{2^{n} q}$ is uniformly convergent on the set $\{q$ : $\left.q<q_{0}\right\}$. Hence, we obtain (5.2).

Fix $0<t \leq 1$. Since $e^{2^{n} q} \rightarrow 1(q \rightarrow 0)$, we have

$$
\lim _{q \rightarrow 0} \frac{\partial P}{\partial q}(t, q)=\frac{\sum_{n=1}^{\infty} 2^{-n(t-1)}}{\sum_{n=1}^{\infty} 2^{-n t}}
$$

Notice that

$$
\sum_{n=1}^{\infty} 2^{-n(t-1)}=\infty, \quad \sum_{n=1}^{\infty} 2^{-n t}=\frac{1}{2^{t}-1}
$$

Hence, (5.3) is proved.
In order to prove (2), we need to show

$$
\lim _{t \rightarrow 0} \frac{\sum_{n=1}^{\infty} 2^{-n(t-1)}}{\sum_{n=1}^{\infty} 2^{-n t}}=\infty
$$

This is analogous to that in (4.7) and is left to the reader.
Observe that

$$
\sum_{n=1}^{\infty} 2^{-n(t-1)} e^{2^{n} q}>2 \sum_{n=1}^{\infty} 2^{-n t} e^{2^{n} q}
$$

As a result,

$$
\frac{\partial P}{\partial q}(t, q)>2
$$

This proves the first part of (3).
Since $\lim _{q \rightarrow-\infty} e^{\left(2^{n}-2\right) q}=0$ for $n \geq 2$, it follows that

$$
\lim _{q \rightarrow-\infty} \frac{\sum_{n=1}^{\infty} 2^{-n(t-1)} e^{2^{n} q}}{\sum_{n=1}^{\infty} 2^{-n t} e^{2^{n} q}}=\lim _{q \rightarrow-\infty} \frac{2^{-(t-1)} e^{2 q}\left(1+\sum_{n=2}^{\infty} 2^{-(n-1)(t-1)} e^{\left(2^{n}-2\right) q}\right)}{2^{-t} e^{2 q}\left(1+\sum_{n=2}^{\infty} 2^{-(n-1) t} e^{\left(2^{n}-2\right) q}\right)}=2
$$

which completes the proof.
Proposition 5.3. For $(t, q) \in D_{1}$,

$$
\begin{equation*}
\frac{\partial P}{\partial t}(t, q)=\frac{(-\log 2) \sum_{n=1}^{\infty} n 2^{-n t} e^{2^{n} q}}{\sum_{n=1}^{\infty} 2^{-n t} e^{2^{n} q}} \tag{5.6}
\end{equation*}
$$

Consequently,
(1) for fixed $t \geq 0$,

$$
\begin{equation*}
\lim _{q \rightarrow-\infty} \frac{\partial P}{\partial t}(t, q)=-\log 2 \tag{5.7}
\end{equation*}
$$

(2) for $t=1$,

$$
\begin{equation*}
\lim _{q \rightarrow 0} \frac{\partial P}{\partial t}(1, q)=-\frac{\log 2}{2} \tag{5.8}
\end{equation*}
$$

Proof. By Abel's test, it follows that the series $\sum_{n=1}^{\infty} n 2^{-n t} e^{2^{n} q}$ converges uniformly with respect to $t$ on the set $D_{1}$. Hence, we get (5.6).

Fix $t \geq 0$. Write

$$
\frac{\sum_{n=1}^{\infty} n 2^{-n t} e^{2^{n} q}}{\sum_{n=1}^{\infty} 2^{-n t} e^{2^{n} q}}=\frac{e^{2 q}\left(2^{-t}+\sum_{n=2}^{\infty} n 2^{-n t} e^{\left(2^{n}-2\right) q}\right)}{e^{2 q}\left(2^{-t}+\sum_{n=2}^{\infty} 2^{-n t} e^{\left(2^{n}-2\right) q}\right)}=\frac{2^{-t}+\sum_{n=2}^{\infty} n 2^{-n t} e^{\left(2^{n}-2\right) q}}{2^{-t}+\sum_{n=2}^{\infty} 2^{-n t} e^{\left(2^{n}-2\right) q}}
$$

Notice that for any $n \geq 2$,

$$
\lim _{q \rightarrow-\infty} e^{\left(2^{n}-2\right) q}=0
$$

From the above, it follows that

$$
\lim _{q \rightarrow-\infty} \frac{\sum_{n=1}^{\infty} n 2^{-n t} e^{2^{n} q}}{\sum_{n=1}^{\infty} 2^{-n t} e^{2^{n} q}}=1
$$

which proves (5.7).
By (5.6), we have

$$
\frac{\partial P}{\partial t}(1, q)=\frac{(-\log 2) \sum_{n=1}^{\infty} n 2^{-n} e^{2^{n} q}}{\sum_{n=1}^{\infty} 2^{-n} e^{2^{n} q}}
$$

Since $e^{2^{n} q} \rightarrow 1(q \rightarrow 0)$ for $n \in \mathbb{N}$ and $\sum_{n=1}^{\infty} 2^{-n}=1$, we have

$$
\begin{equation*}
\lim _{q \rightarrow 0} \frac{\partial P}{\partial t}(1, q)=(-\log 2) \sum_{n=1}^{\infty} n 2^{-n}=-\frac{\log 2}{2} \tag{5.9}
\end{equation*}
$$

Proposition 5.4. Let $\tilde{D}=\{(t, q) \in D: 0 \leq t \leq 1\}$. For any $\xi \in(2, \infty)$, the system

$$
\left\{\begin{array}{l}
P(t, q)=q \xi  \tag{5.10}\\
\frac{\partial P}{\partial q}(t, q)=\xi
\end{array}\right.
$$

admits a unique solution $(t(\xi), q(\xi)) \in \tilde{D}$. Further, the functions $t(\xi)$ and $q(\xi)$ are analytic.

### 5.1. Proofs of Theorem 1.3 (1) and (2)

It follows from the Birkhoff ergodic theorem that for Lebesgue almost all $x$ in $(0,1]$,

$$
\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{j=1}^{n} 2^{d_{j}(x)}=\int 2^{\left\lceil-\log _{2} x\right\rceil} \mathrm{d} x=\infty
$$

Hence,

$$
\operatorname{dim}_{H} E_{\varphi}(\infty)=\operatorname{dim}_{H}\{x \in(0,1]: \bar{\varphi}(x)=\infty\}=1
$$

Proposition 5.5. The function $t(\xi)$ is strictly incresing on $(2, \infty)$.
Proof. From the analytic area of $P(t, q)$, we know that $q(\xi) \leq 0$. Suppose there exists $\xi_{1}<\infty$ such that $q\left(\xi_{1}\right)=0$. Then $P\left(t\left(\xi_{1}\right), 0\right)=0$ by Proposition 5.4. Hence, we have $t\left(\xi_{1}\right)=1$ and $(\partial P / \partial q)(1,0)=\xi_{1}$. However, by (5.3), we have

$$
\lim _{(t, q) \rightarrow(1,0)} \frac{\partial P}{\partial q}(t, q)=\infty
$$

This contradicts to the hypothesis that $\xi_{1}<\infty$. Thus $t^{\prime}(\xi)>0$.

### 5.2. Proofs of Theorem 1.3 (3) and (4)

Proposition 5.6. We have

$$
\begin{equation*}
\lim _{\xi \rightarrow 2} t(\xi)=0, \quad \lim _{\xi \rightarrow 2} q(\xi)=-\infty \tag{5.11}
\end{equation*}
$$

## Furthermore,

$$
\lim _{\xi \rightarrow 2} t^{\prime}(\xi)=\infty
$$

Proof. To show the first formula in (5.11), we use the same method as in the proof of Proposition 4.5. Since $\xi \mapsto t(\xi)$ is increasing and analytic on $(2, \infty)$, we can write its inverse function $\xi=\xi(t)$. Then $\xi^{\prime}(t)>0$ and

$$
\xi(t)=\frac{P(t, q(t))}{q(t)}=\frac{\partial P}{\partial q}(t, q(t))
$$

We conclude from (5.5) that

$$
\lim _{q \rightarrow-\infty} \frac{\partial P}{\partial q}(0, q)=2
$$

hence that $\lim _{t \rightarrow 0} \xi(t)=2$, and finally that $\lim _{\xi \rightarrow 2} t(\xi)=0$.
Now suppose that there exists a subsequence $\left\{\xi_{n_{k}}\right\}_{k \geq 1}$, such that

$$
\lim _{k \rightarrow \infty} \xi_{n_{k}}=2, \quad \lim _{k \rightarrow \infty} q\left(\xi_{n_{k}}\right)=M>-\infty
$$

Since $\lim _{\xi \rightarrow 2} t(\xi)=0$, it follows that $\lim _{k \rightarrow \infty} t\left(\xi_{n_{k}}\right)=0$. By Proposition 5.4,

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \frac{\partial P}{\partial q}\left(t\left(\xi_{n_{k}}\right), q\left(\xi_{n_{k}}\right)\right)=\lim _{k \rightarrow \infty} \xi_{n_{k}}=2 \tag{5.12}
\end{equation*}
$$

If $M=0$, then by (5.4), we have

$$
\lim _{k \rightarrow \infty} \frac{\partial P}{\partial q}\left(t\left(\xi_{n_{k}}\right), q\left(\xi_{n_{k}}\right)\right)=\lim _{(t, q) \rightarrow(0,0)} \frac{\partial P}{\partial q}(t, q)=\infty
$$

which contradicts to (5.12). If $M<0$, then by Proposition 5.2 (3), we have

$$
\lim _{k \rightarrow \infty} \frac{\partial P}{\partial q}\left(t\left(\xi_{n_{k}}\right), q\left(\xi_{n_{k}}\right)\right)=\frac{\partial P}{\partial q}(0, M)>2
$$

which is also a contradiction to (5.12). Hence, $q(\xi) \rightarrow-\infty(\xi \rightarrow 2)$.
Applying the second formula in (5.11) and combining (4.9) and (5.7), we conclude that

$$
\lim _{\xi \rightarrow 2} t^{\prime}(\xi)=\infty
$$

Proposition 5.7. We have

$$
\begin{equation*}
\lim _{\xi \rightarrow \infty} t(\xi)=1, \quad \lim _{\xi \rightarrow \infty} q(\xi)=0 \tag{5.13}
\end{equation*}
$$

Furthermore,

$$
\lim _{\xi \rightarrow \infty} t^{\prime}(\xi)=0
$$

Proof. Recall that for any $\xi>2$,

$$
\left\{\begin{array}{l}
P(t(\xi), q(\xi))=q(\xi) \xi \\
\frac{\partial P}{\partial q}(t(\xi), q(\xi))=\xi
\end{array}\right.
$$

Suppose $(t(\xi), q(\xi)) \rightarrow\left(t_{0}, q_{0}\right)$ as $\xi \rightarrow \infty$. The analyticity of $t(\xi)$ and $q(\xi)$ implies that $0<t_{0} \leq 1$ and $q_{0} \leq 0$. Suppose $q_{0}<0$. Then by (5.2) and (5.5), we have

$$
\lim _{(t, q) \rightarrow\left(t_{0}, q_{0}\right)} \frac{\partial P}{\partial q}(t, q)<\infty
$$

which is a contradiction to

$$
\lim _{\xi \rightarrow \infty} \frac{\partial P}{\partial q}(t, q)=\lim _{\xi \rightarrow \infty} \xi=\infty
$$

Thus $q_{0}=0$. For any $\xi>2$, since $q(\xi) \xi<0$ and $P\left(t_{0}, 0\right) \geq 0$, we have

$$
P\left(t_{0}, 0\right)=\lim _{\xi \rightarrow \infty} q(\xi) \xi=0
$$

Since $P(1,0)=0$ and $(\partial P / \partial q)(t, q) \rightarrow \infty$ as $(t, q) \rightarrow(1,0)$, we have $\left(t_{0}, q_{0}\right)=(1,0)$, which completes the proof of (5.13).

By (5.8) and (4.9), we have

$$
\lim _{\xi \rightarrow \infty} t^{\prime}(\xi)=0
$$

Applying similar arguments to the proof of Theorem 4.1 yields

$$
\operatorname{dim}_{H} E_{\varphi}(2)=0
$$
