# SOLUTIONS OF AN ELLIPTIC SYSTEM WITH A NEARLY CRITICAL EXPONENT 

I.A. GUERRA

Abstract. Consider the problem

$$
\begin{aligned}
-\Delta u_{\epsilon} & =v_{\epsilon}^{p} \quad v_{\epsilon}>0 \quad \text { in } \Omega, \\
-\Delta v_{\epsilon} & =u_{\epsilon}^{q_{\epsilon}} \quad u_{\epsilon}>0 \quad \text { in } \Omega, \\
u_{\epsilon} & =v_{\epsilon}=0 \quad \text { on } \partial \Omega,
\end{aligned}
$$

where $\Omega$ is a bounded convex domain in $\mathbb{R}^{N}, N>2$, with smooth boundary $\partial \Omega$. Here $p, q_{\epsilon}>0$, and

$$
\epsilon:=\frac{N}{p+1}+\frac{N}{q_{\epsilon}+1}-(N-2) .
$$

This problem has positive solutions for $\epsilon>0$ (with $p q_{\epsilon}>1$ ) and no non-trivial solution for $\epsilon \leq 0$. We study the asymptotic behaviour of least energy solutions as $\epsilon \rightarrow 0^{+}$. These solutions are shown to blow-up at exactly one point, and the location of this point is characterized. In addition, the shape and exact rates for blowing up are given.
Résumé. Considéré le problème

$$
\begin{aligned}
-\Delta u_{\epsilon} & =v_{\epsilon}^{p} \quad v_{\epsilon}>0 \text { en } \Omega, \\
-\Delta v_{\epsilon} & =u_{\epsilon}^{q_{\epsilon}} u_{\epsilon}>0 \text { en } \Omega, \\
u_{\epsilon} & =v_{\epsilon}=0 \text { sur } \partial \Omega,
\end{aligned}
$$

où $\Omega$ est un domaine convexe et borné de $\mathbb{R}^{N}, N>2$, avec la frontière régulière $\partial \Omega$. Ici $p, q_{\epsilon}>0$, et

$$
\epsilon:=\frac{N}{p+1}+\frac{N}{q_{\epsilon}+1}-(N-2) .
$$

Ce problème a les solutions positives pour $\epsilon>0$ (avec $p q_{\epsilon}>1$ ) et non pas de solution non-trivial pour $\epsilon \leq 0$. Nous étudions le comportement asymptotique de solutions d'énergie minimale quand $\epsilon \rightarrow 0^{+}$. Ces solutions explosent en un seul point, et la localisation de ce point est characterisé. De plus, la forme et le rythme d'explosion sont donnés.

## 1. Introduction

We consider the elliptic system

$$
\begin{align*}
-\Delta u_{\epsilon} & =v_{\epsilon}^{p} \quad v_{\epsilon}>0 \quad \text { in } \quad \Omega,  \tag{1.1}\\
-\Delta v_{\epsilon} & =u_{\epsilon}^{q_{\epsilon}} \quad u_{\epsilon}>0 \quad \text { in } \Omega,  \tag{1.2}\\
u_{\epsilon} & =v_{\epsilon}=0 \quad \text { on } \quad \partial \Omega, \tag{1.3}
\end{align*}
$$

[^0]Key words and phrases. Semilinear elliptic system, asymptotic behaviour, critical exponent. This research was supported by FONDECYT 3040059.
where $\Omega$ is a bounded convex domain in $\mathbb{R}^{N}, N>2$, with smooth boundary $\partial \Omega$. Here $p, q_{\epsilon}>0$, and

$$
\begin{equation*}
\epsilon:=\frac{N}{p+1}+\frac{N}{q_{\epsilon}+1}-(N-2) . \tag{1.4}
\end{equation*}
$$

When $\epsilon \leq 0$, there is no solution for (1.1)-(1.3), see [18] and [22]. On the other hand when $\epsilon>0$, we can prove existence of solutions obtained by the variational method. In fact, for $\epsilon>0$, the embedding $W^{2, \frac{p+1}{p}}(\Omega) \hookrightarrow L^{q_{\epsilon}+1}(\Omega)$ is compact for any $q_{\epsilon}+1>(p+1) / p$, that is $p q_{\epsilon}>1$. Using this, it is not difficult to show that there exists a function $\bar{u}_{\epsilon}$ positive solution of the variational problem

$$
\begin{equation*}
S_{\epsilon}(\Omega)=\inf \left\{\left.\|\Delta u\|_{L^{\frac{p+1}{p}}(\Omega)} \right\rvert\, u \in W^{2, \frac{p+1}{p}}(\Omega), \quad\|u\|_{L^{q_{\epsilon}+1}(\Omega)}=1\right\} \tag{1.5}
\end{equation*}
$$

see for example [23]. This solution satisfies $-\Delta \bar{u}_{\epsilon}=\bar{v}_{\epsilon}^{p},-\Delta \bar{v}_{\epsilon}=S_{\epsilon}(\Omega) \bar{u}_{\epsilon}^{q_{\epsilon}}$, in $\Omega$ and $\bar{u}_{\epsilon}=\bar{v}_{\epsilon}=0$ on $\partial \Omega$. After a suitable multiples of $\bar{u}_{\epsilon}$ and $\bar{v}_{\epsilon}$, we obtain $u_{\epsilon}$ and $v_{\epsilon}$ solving (1.1)-(1.3). We call $\left(u_{\epsilon}, v_{\epsilon}\right)$ the least energy solution to (1.1)-(1.3). For others existence results, we refer to [4], [7], 9], 15], and [19].

Note that by setting $v_{\epsilon}=\left(-\Delta u_{\epsilon}\right)^{1 / p}$, we can write the system (1.1)-(1.3) only in terms of $u_{\epsilon}$, that is

$$
\begin{align*}
-\Delta\left(-\Delta u_{\epsilon}\right)^{1 / p} & =u_{\epsilon}^{q_{\epsilon}} \quad u_{\epsilon}>0 \quad \text { in } \quad \Omega  \tag{1.6}\\
u_{\epsilon} & =\Delta u_{\epsilon}=0 \quad \text { on } \partial \Omega . \tag{1.7}
\end{align*}
$$

Concerning the least energy solutions, in [23] it was proved that $S_{\epsilon}(\Omega) \rightarrow S$ as $\epsilon \downarrow 0$, where $S$ is independent of $\Omega$ and moreover is the best Sobolev constant for the inequality

$$
\begin{equation*}
\|u\|_{L^{q+1}\left(\mathbb{R}^{N}\right)} \leq S^{-\frac{p}{p+1}}\|\Delta u\|_{L^{\frac{p+1}{p}}\left(\mathbb{R}^{N}\right)} \tag{1.8}
\end{equation*}
$$

with $p, q, N$ satisfying

$$
\begin{equation*}
\frac{N}{p+1}+\frac{N}{q+1}-(N-2)=0 \tag{1.9}
\end{equation*}
$$

This shows that the sequence $\left\{u_{\epsilon}\right\}_{\epsilon>0}$ of least energy solutions of (1.6)-(1.7) satisfy

$$
\begin{equation*}
S_{\epsilon}(\Omega)=\frac{\int_{\Omega}\left|\Delta u_{\epsilon}\right|^{\frac{p+1}{p}} d x}{\left\|u_{\epsilon}\right\|_{L^{\frac{p+1}{p}}}^{q_{\epsilon}+1}(\Omega)}=S+o(1) \quad \text { as } \quad \epsilon \rightarrow 0 \tag{1.10}
\end{equation*}
$$

Relation (1.9) defines a curve in $\mathbb{R}_{+}^{2}$, for the variables $p$ and $q$. This curve is the so-called Sobolev Critical Hyperbola. By symmetry, we assume without restriction that

$$
\begin{equation*}
2 /(N-2)<p \leq p^{*}:=(N+2) /(N-2) . \tag{1.11}
\end{equation*}
$$

For each fixed value of $p$, the strict inequality gives a lower bound for the dimension, i.e. $N>\max \{2,2(p+1) / p\}$.

In this article, we shall study in detail the asymptotic behaviour of the variational solution $u_{\epsilon}$, of (1.6)-(1.7) as $\epsilon \downarrow 0$, that is, as $q_{\epsilon}$ approaches from below to $q$ given by the Sobolev Critical Hyperbola (1.9).

The asymptotic behaviour of the equation (1.6)-(1.7) as $\epsilon \downarrow 0$ has already been studied for $p=p^{*}$ and $p=1$. Next we recall some of these results to introduce ours.

The case $p=p^{*}$ is equivalent to consider the single equation

$$
-\Delta u_{\epsilon}=u_{\epsilon}^{p^{*}-\epsilon} \quad \text { in } \quad \Omega, \quad \text { and } \quad u_{\epsilon}=0 \quad \text { on } \quad \partial \Omega .
$$

This problem was studied in [1, 10, 13, 20. There, exact rates of blow-up were given and the location of blow-up points were characterized. One key ingredient was the Pohozaev identity and the observation that the solution $u_{\epsilon}$, scaled in the form $\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{-1} u_{\epsilon}$ converges to $U$ solution of

$$
\begin{align*}
-\Delta U & =U^{p^{*}}, \quad U(y)>0 \quad \text { for } \quad y \in \mathbb{R}^{N}  \tag{1.12}\\
U(0) & =1, \quad U \rightarrow 0, \quad \text { as } \quad|y| \rightarrow \infty \tag{1.13}
\end{align*}
$$

which is unique, explicit, and radially symmetric. For the location of blow-up and the shape of the solution away of the singularity, it was proved that a scaled $u_{\epsilon}$, given by $\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} u_{\epsilon}$, converges to the Green's function $G$, solution of $-\Delta G(x, \cdot)=\delta_{x}$ in $\Omega, G(x, \cdot)=0$ on $\partial \Omega$. The location of blowing-up points are the critical points of $\phi(x):=g(x, x)$ (in fact their minima, see [10]), where $g(x, y)$ is the regular part of $G(x, y)$, i.e

$$
g(x, y)=G(x, y)-\frac{1}{(N-2) \sigma_{N}|x-y|^{N-2}}
$$

In [6], a similar result was proven in the case $p=1,(N>4)$, where the problem is reduced to study (1.12)-(1.13) with the operator $\Delta^{2}$ instead of $-\Delta$. Both cases give the blow-up rate

$$
\epsilon\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{2} \rightarrow C \quad \text { as } \quad \epsilon \rightarrow 0
$$

for some explicit $C:=C(p, N, \Omega)>0$. We can ask ourselves if this behaviour is universal. We will see later that this is only a coincide.

Mimicking the above argument, we will study the asymptotic behaviour of the solution $u_{\epsilon}$ of (1.6)-(1.7) as $\epsilon \downarrow 0$. We shall show that $\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{-1} u_{\epsilon}$ converges, as $\epsilon \downarrow 0$, to the solution $U$ of the problem

$$
\begin{align*}
-\Delta U & =V^{p}, \quad V(y)>0 \quad \text { for } \quad y \in \mathbb{R}^{N}  \tag{1.14}\\
-\Delta V & =U^{q}, \quad U(y)>0 \quad \text { for } \quad y \in \mathbb{R}^{N}  \tag{1.15}\\
U(0) & =1, \quad U \rightarrow 0, \quad V \rightarrow 0 \quad \text { as } \quad|y| \rightarrow \infty \tag{1.16}
\end{align*}
$$

In (5), it was proved that $U$ and $V$ are radially symmetric, if $p \geq 1$ and $U \in L^{q+1}\left(\mathbb{R}^{N}\right)$ and $V \in L^{p+1}\left(\mathbb{R}^{N}\right)$. This is the case when considering least energy solutions, see details in section 2 Thus $U(r):=U(y)$ and $V(r):=V(y)$ with $r=|y|$, moreover $U$ and $V$ are unique, and decreasing in $r$, see [16, 23]. There exist no explicit form of $(U, V)$ for all $p \geq 1$, however to carry out the analysis it is sufficient to know the
asymptotic behaviour of $(U, V)$ as $r \rightarrow \infty$, which was studied in [16]. They found

$$
\lim _{r \rightarrow \infty} r^{N-2} V(r)=a \quad \text { and } \quad\left\{\begin{array}{lll}
\lim _{r \rightarrow \infty} r^{N-2} U(r)=b & \text { if } & p>\frac{N}{N-2}  \tag{1.17}\\
\lim _{r \rightarrow \infty} \frac{r^{N-2}}{\log r} U(r)=b & \text { if } & p=\frac{N}{N-2} \\
\lim _{r \rightarrow \infty} r^{p(N-2)-2} U(r)=b & \text { if } \quad \frac{2}{N-2}<p<\frac{N}{N-2}
\end{array}\right.
$$

The aim of this paper is to show the following results.
Theorem 1.1. Let $u_{\epsilon}$ be a least energy solution of (1.6)-(1.7) and $p \geq 1$. Then
a) there exists $x_{0} \in \Omega$ such that, after passing to a subsequence, we have
i) $u_{\epsilon} \rightarrow 0 \in C^{1}\left(\Omega \backslash\left\{x_{0}\right\}\right)$,
ii) $v_{\epsilon}=\left|\Delta u_{\epsilon}\right|^{\frac{1}{p}} \rightarrow 0 \in C^{1}\left(\Omega \backslash\left\{x_{0}\right\}\right)$
as $\epsilon \rightarrow 0$ and

$$
\text { iii) } \quad\left|\Delta u_{\epsilon}\right|^{\frac{p+1}{p}} \rightarrow\|V\|_{L^{p+1}\left(\mathbb{R}^{N}\right)}^{p+1} \delta_{x_{0}} \quad \text { as } \quad \epsilon \rightarrow 0
$$

in the sense of distributions.
b) $x_{0}$ is a critical point of

$$
\begin{align*}
& \phi(x):=g(x, x) \quad \text { if } \quad p \in[N /(N-2),(N+2) /(N-2)) \quad \text { and }  \tag{1.18}\\
& \tilde{\phi}(x):=\tilde{g}(x, x) \quad \text { if } \quad p \in(2 /(N-2), N /(N-2)) \tag{1.19}
\end{align*}
$$

for $x \in \Omega$. The function $\tilde{g}(x, y)$ is defined for $p \in(2 /(N-2), N /(N-2))$ by

$$
\tilde{g}(x, y)=\tilde{G}(x, y)-\frac{1}{(p(N-2)-2)(N-p(N-2))(N-2)^{p} \sigma_{N}^{p}|x-y|^{p(N-2)-2}}
$$

where $-\Delta \tilde{G}(x, \cdot)=G^{p}(x, \cdot)$ in $\Omega, \tilde{G}(x, \cdot)=0$ on $\partial \Omega$.
We observe that regularity of $\tilde{\phi}$ is needed to compute its critical points in b). We show next that $\tilde{\phi}$ is regular. By definition of $\tilde{G}$, we have

$$
\begin{equation*}
\lim _{y \rightarrow x}|x-y|^{(p-1)(N-2)} \Delta \tilde{g}(x, y)=-\frac{p g(x, x)}{\left((N-2) \sigma_{N}\right)^{p-1}} \tag{1.20}
\end{equation*}
$$

for $x \in \Omega$. Thus $-\Delta \tilde{g}(x, \cdot) \in L^{q}(\Omega)$ for any $q \in(N / 2, N /(p(N-2)-N+2))$. This implies, by regularity, that $\tilde{g}(x, \cdot) \in L^{\infty}(\Omega)$ and therefore $\tilde{\phi}(x)=\tilde{g}(x, x), x \in \Omega$ is bounded. In addition, we define

$$
\begin{equation*}
\hat{g}(x, y)=\tilde{g}(x, y)+\frac{p g(x, x)|x-y|^{N-p(N-2)}}{(N-p(N-2))(2 N-p(N-2)-2)\left((N-2) \sigma_{N}\right)^{p-1}} \tag{1.21}
\end{equation*}
$$

and we have for any $x \in \Omega$ that

$$
\begin{equation*}
\lim _{y \rightarrow x}|x-y|^{(p-2)(N-2)} \Delta \hat{g}(x, y)=-\frac{p(p-1) g(x, x)}{\left((N-2) \sigma_{N}\right)^{p-2}} \tag{1.22}
\end{equation*}
$$

Thus $\hat{g}(x, y)$ is regular in $y$ for $x$ fixed. Since $N>p(N-2)$, we take first $\underset{\sim}{y}=x$ in (1.21) and then the gradient and we find $\nabla_{x} \tilde{g}(x, x)=\nabla_{x} \hat{g}(x, x)$. Hence $\tilde{\phi}(x)$ is regular.

To state the next theorems we denote

$$
\alpha=\frac{N}{q+1} \quad \text { and } \quad \beta=\frac{N}{p+1}
$$

so the critical hyperbola (1.9) takes the form $\alpha+\beta=N-2$.
Theorem 1.2. Let the assumptions of Theorem 1.1 be satisfied. Then

$$
\left\{\begin{array}{l}
\lim _{\epsilon \rightarrow 0^{+}} \epsilon\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{(N-2)}{\alpha}(\Omega)}=S^{\frac{1-p q}{p(q+1)}}\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{q}\|V\|_{L^{p}\left(\mathbb{R}^{N}\right)}^{p}\left|\phi\left(x_{0}\right)\right| \quad \text { if } p>\frac{N}{N-2} \\
\lim _{\epsilon \rightarrow 0^{+}} \epsilon \frac{\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\alpha}}{\log \left(\left\|u_{\epsilon}\right\|_{\left.L^{\infty}(\Omega)\right)}^{\alpha}\right.}=\frac{1}{\alpha} a^{\frac{N}{N-2}} S^{\frac{1-p q}{p(q+1)}}\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{q}\left|\phi\left(x_{0}\right)\right| \quad \text { if } \quad p=\frac{N}{N-2} \\
\lim _{\epsilon \rightarrow 0^{+}} \epsilon\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{p(N-2)-2}{\alpha}}=S^{\frac{1-p q}{p(q+1)}}\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{q(p+1)}\left|\tilde{\phi}\left(x_{0}\right)\right| \quad \text { if } \quad p<\frac{N}{N-2} .
\end{array}\right.
$$

In particular taking $p=p^{*}$, and using (1.9) we find that $q=p^{*}$. We recover the results in [13, 20], that is

$$
\begin{equation*}
\epsilon\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{2} \rightarrow C \quad \text { as } \quad \epsilon \rightarrow 0 \tag{1.23}
\end{equation*}
$$

for some explicitly given $C>0$. See also [1] for the case $\Omega=B_{R}$.
When $N>4$, we can take $p=1$, and use (1.11) to find that $q=(N+4) /(N-4)$. Here we recover the result in [2, 6], where they prove that (1.23) holds for some $C>0$.
Theorem 1.3. Let the assumptions of Theorem 1.1 be satisfied. Then

$$
\begin{align*}
& \lim _{\epsilon \rightarrow 0}\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} v_{\epsilon}(x)=\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{q} G\left(x, x_{0}\right), \quad \text { and }  \tag{1.24}\\
& \left\{\begin{array}{l}
\lim _{\epsilon \rightarrow 0}\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}} u_{\epsilon}(x)=\|V\|_{L^{p}\left(\mathbb{R}^{N}\right)}^{p} G\left(x, x_{0}\right) \quad \text { if } \quad p>\frac{N}{N-2} \\
\lim _{\epsilon \rightarrow 0} \frac{\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}(\Omega)}}{\log \left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}} u_{\epsilon}(x)=\frac{1}{\alpha} a^{\frac{N}{N-2}} G\left(x, x_{0}\right) \quad \text { if } \quad p=\frac{N}{N-2} \\
\lim _{\epsilon \rightarrow 0}\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{1}{\alpha}(\beta+p(N-2)-N)} u_{\epsilon}(x)=\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{p q} \tilde{G}\left(x, x_{0}\right) \quad \text { if } \quad p<\frac{N}{N-2}
\end{array}\right. \tag{1.25}
\end{align*}
$$

where all the convergences in $C^{1, \alpha}(w)$ with $w$ any neighborhood of $\partial \Omega$ not containing $x_{0}$.
Remark 1.4. For $p<\frac{N}{N-2}$, the convergence in (1.25) can be improved to $C^{3, \alpha}(\omega)$. See the proof of the theorem.
Remark 1.5. By (2.13), we find that $\lim _{\epsilon \rightarrow 0}\left\|v_{\epsilon}\right\|_{L^{\infty}(\Omega)}=V(0) \lim _{\epsilon \rightarrow 0}\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}}$. So, in addition, when $p=1$ we have that

$$
\epsilon\left\|v_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{2(N-4) / N} \rightarrow C V(0)^{2(N-4) / N} \quad \text { as } \quad \epsilon \rightarrow 0 .
$$

We can extend these results to the problem

$$
\begin{align*}
-\Delta\left(-\Delta u_{\epsilon}\right)^{1 / p} & =u_{\epsilon}^{q}+\epsilon u_{\epsilon} \quad u_{\epsilon}>0 \quad \text { in } \quad \Omega  \tag{1.26}\\
u_{\epsilon} & =\Delta u_{\epsilon}=0 \quad \text { on } \quad \partial \Omega \tag{1.27}
\end{align*}
$$

with $\epsilon \rightarrow 0$. The existence of positive solutions for this problem can be found in [15] and [19] in the case of a ball. See [14] for related results for $p=1$.

Theorem 1.6. Let the assumptions of Theorem 1.1 be satisfied. Then

$$
\begin{align*}
& \lim _{\epsilon \rightarrow 0^{+}} \epsilon\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{2-\frac{2}{\alpha}}=\|U\|_{L^{2}\left(\mathbb{R}^{N}\right)}^{-2}\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{q}\|V\|_{L^{p}\left(\mathbb{R}^{N}\right)}^{p}\left|\phi\left(x_{0}\right)\right| \quad \text { if } \quad p>\frac{N}{N-2} \\
& \text { and } \quad \alpha>1, N>4  \tag{1.28}\\
& \lim _{\epsilon \rightarrow 0^{+}} \epsilon \frac{\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{2-\frac{2}{\alpha}}}{\log \left(\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}\right)}=\frac{1}{\alpha} a^{\frac{N}{N-2}}\|U\|_{L^{2}\left(\mathbb{R}^{N}\right)}^{-2}\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{q}\left|\phi\left(x_{0}\right)\right| \quad \text { if } \quad p=\frac{N}{N-2} \\
& \text { and } \quad 2-\frac{2}{\alpha}=3-\left(\frac{N}{N-2}\right)^{2}>0,  \tag{1.29}\\
& \lim _{\epsilon \rightarrow 0^{+}} \epsilon\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)^{\alpha}}^{2-\frac{2+N-p(N-2)}{\alpha}}=\|U\|_{L^{2}\left(\mathbb{R}^{N}\right)}^{-2}\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{q(p+1)}\left|\tilde{\phi}\left(x_{0}\right)\right| \quad \text { if } \quad \frac{N+4}{2(N-2)}<p<\frac{N}{N-2} \\
& \text { and } \quad \alpha>\frac{2+N-p(N-2)}{2}  \tag{1.30}\\
& \lim _{\epsilon \rightarrow 0^{+}} \epsilon \log \left(\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}\right)=\frac{\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{q}\|V\|_{L^{p}\left(\mathbb{R}^{N}\right)}^{p}}{b^{2}}\left|\phi\left(x_{0}\right)\right| \quad \text { if } \quad N=4, p=q=3,  \tag{1.31}\\
& \begin{array}{c}
\lim _{\epsilon \rightarrow 0^{+}} \epsilon \log \left(\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}\right)\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{3-q}{2}}=\frac{\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{q(p+1)}}{b^{2}}\left|\tilde{\phi}\left(x_{0}\right)\right| \quad \text { if } p=\frac{N+4}{2(N-2)}<\frac{N}{N-2}, \\
\text { and } q \leq 3
\end{array} \tag{1.32}
\end{align*}
$$

Note that $N>4$ (integer) is equivalent to $3-(N /(N-2))^{2}>0$ and also to $(N+4) /(2(N-2))<N /(N-2)$. This implies that (1.29) holds for $p=N /(N-2)$ and $N>4$, and (1.32) holds for $p=\frac{N+4}{2(N-2)}, q \leq 3$ and $N>4$.

For example, $p=1$ gives $q+1=2 N /(N-4)$ and provided that $N>8$, we get

$$
\lim _{\epsilon \rightarrow 0^{+}} \epsilon\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{2(N-8)}{N-4}}=C_{1}\left|\tilde{\phi}\left(x_{0}\right)\right| .
$$

For $N=8$ and $p=1$, we have

$$
\lim _{\epsilon \rightarrow 0^{+}} \epsilon \log \left(\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}\right)=C_{1}\left|\tilde{\phi}\left(x_{0}\right)\right| .
$$

## 2. Preliminaries

Before proving the main theorem, we need some properties of $u_{\epsilon}$. Using that $u_{\epsilon}$ is a minimizing sequence, we have

$$
\int_{\Omega}\left(\Delta u_{\epsilon}\right)^{\frac{p+1}{p}} d x=\int_{\Omega} v_{\epsilon} \Delta u_{\epsilon} d x=\int_{\Omega} u_{\epsilon} \Delta v_{\epsilon} d x=\int_{\Omega} u_{\epsilon}^{q_{\epsilon}+1} d x .
$$

Then $[S+o(1)]\left\|u_{\epsilon}\right\|_{L^{q_{\epsilon}+1}(\Omega)}^{\frac{p+1}{p}}=\left\|u_{\epsilon}\right\|_{L^{q_{\epsilon}+1}(\Omega)}^{q_{\epsilon}+1}$ implies

$$
\begin{equation*}
\lim _{\epsilon \rightarrow 0} \int_{\Omega} u_{\epsilon}^{q_{\epsilon}+1} d x=S^{\frac{p q-1}{p(q+1)}} . \tag{2.1}
\end{equation*}
$$

Lemma 2.1. The minimizing sequence $u_{\epsilon}$ of (1.10) is such that

$$
\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} \rightarrow \infty
$$

moreover $\left\|\left(-\Delta u_{\epsilon}\right)^{1 / p}\right\|_{L^{\infty}(\Omega)}=\left\|v_{\epsilon}\right\|_{L^{\infty}(\Omega)} \rightarrow \infty \quad$ as $\quad \epsilon \rightarrow 0$.
Proof. If $\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} \rightarrow \infty$ then by regularity, we find $\left\|v_{\epsilon}\right\|_{L^{\infty}(\Omega)} \rightarrow \infty$, see [12, Theorem 3.7]. Now, assume that $\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} \leq M$ and $\left\|v_{\epsilon}\right\|_{L^{\infty}(\Omega)} \leq M$, by elliptic regularity, we have that

$$
\left\|v_{\epsilon}\right\|_{C^{2+\alpha}(\bar{\Omega})} \leq M \quad \text { and } \quad\left\|u_{\epsilon}\right\|_{C^{2+\alpha}(\bar{\Omega})} \leq M
$$

with $\alpha \in(0,1)$ and some constant $M$. This implies that there exists $u^{*}, v^{*} \in C^{2}(\bar{\Omega})$, such that

$$
u_{\epsilon} \rightarrow u^{*} \quad \text { in } \quad C^{2}(\bar{\Omega}), \quad v_{\epsilon} \rightarrow v^{*} \quad \text { in } \quad C^{2}(\bar{\Omega}) \quad \text { as } \epsilon \rightarrow 0
$$

Hence $u^{*}$ satifies

$$
0 \neq \int_{\Omega}\left(\Delta u^{*}\right)^{\frac{p+1}{p}} d x=S\left[\int_{\Omega}\left(u^{*}\right)^{q+1} d x\right]^{\frac{(p+1)}{p(q+1)}}
$$

which contradicts that $S$ can be achieved by a minimizer in a bounded domain, see [23]. In other words there exists no non trivial solution for

$$
\begin{align*}
-\Delta u^{*} & =\left(v^{*}\right)^{p}, \quad v>0 \quad \text { in } \Omega  \tag{2.2}\\
-\Delta v^{*} & =\left(u^{*}\right)^{q}, \quad u>0 \quad \text { in } \Omega  \tag{2.3}\\
u^{*} & =v^{*}=0 \quad \text { on } \partial \Omega \tag{2.4}
\end{align*}
$$

in a convex bounded domain, with $p, q$ satisfying (1.9), see [18], [22].
For any $\epsilon>0$, let $\left(u_{\epsilon}, v_{\epsilon}\right)$ be a solution of (1.1)(1.3). By the Pohozaev inequality, see [18] or [22], we have for any $\tilde{\alpha}, \tilde{\beta} \in \mathbb{R}$ that

$$
\begin{array}{r}
\left(\frac{N}{q_{\epsilon}+1}-\tilde{\alpha}\right) \int_{\Omega} u_{\epsilon}^{q_{\epsilon}+1} d x+\left(\frac{N}{p+1}-\tilde{\beta}\right) \int_{\Omega} v_{\epsilon}^{p+1} d x \\
+(N-2-\tilde{\alpha}-\tilde{\beta}) \int_{\Omega}\left(\nabla u_{\epsilon}, \nabla v_{\epsilon}\right) d x=-\int_{\partial \Omega}\left(\nabla u_{\epsilon}, n\right)\left(\nabla v_{\epsilon}, x-y\right) d s . \tag{2.6}
\end{array}
$$

We choose $\tilde{\alpha}+\tilde{\beta}=N-2, \tilde{\alpha}=\alpha$ and so $\tilde{\beta}=\beta$. This implies that

$$
\begin{equation*}
\epsilon \int_{\Omega} u_{\epsilon}^{q_{\epsilon}+1} d x=-\int_{\partial \Omega} \frac{\partial u_{\epsilon}}{\partial n} \frac{\partial v_{\epsilon}}{\partial n}(n, x-y) d s \tag{2.7}
\end{equation*}
$$

Since $u_{\epsilon}$ becomes unbounded as $\epsilon \rightarrow 0$ we choose $\mu=\mu(\epsilon)$ and $x_{\epsilon} \in \Omega$ such that

$$
\mu^{\alpha_{\epsilon}} u_{\epsilon}\left(x_{\epsilon}\right)=1
$$

where $\alpha_{\epsilon}=N /\left(q_{\epsilon}+1\right)$. Note that $\mu \rightarrow 0$ as $\epsilon \rightarrow 0$.
First we claim that $x_{\epsilon}$ stays away from the boundary. This is consequence of moving plane method and interior estimates [8], [1]. Let $\phi_{1}$ the positive eigenvalue
of $\left(-\Delta, H_{0}^{1}(\Omega)\right)$, normalized to $\max _{x \in \Omega} \phi_{1}(x)=1$. Since $p \geq 1$, multiplying by $\phi_{1}$ we obtain

$$
\begin{aligned}
\lambda_{1} \int_{\Omega} u_{\epsilon} \phi_{1} & =\int_{\Omega} v_{\epsilon}^{p} \phi_{1} \geq 2 \lambda_{1} \int_{\Omega} v_{\epsilon} \phi_{1}-C \int_{\Omega} \phi_{1} \\
\lambda_{1} \int_{\Omega} v_{\epsilon} \phi_{1} & =\int_{\Omega} u_{\epsilon}^{q_{\epsilon}} \phi_{1} \geq 2 \lambda_{1} \int_{\Omega} u_{\epsilon} \phi_{1}-C \int_{\Omega} \phi_{1}
\end{aligned}
$$

for some $C=C\left(p, q, \lambda_{1}\right)>0$. Hence $\int_{\Omega} u_{\epsilon} \phi_{1} \leq\left(C / \lambda_{1}\right) \int_{\Omega} \phi_{1}$ which implies $\int_{\Omega^{\prime}} u_{\epsilon} \leq$ $C\left(\Omega^{\prime}\right)$ with $\Omega^{\prime} \subset \Omega$ and $\int_{\Omega^{\prime}} v_{\epsilon} \leq C\left(\Omega^{\prime}\right)$. Using the moving planes method [11, we find that there exist $t_{0} \alpha>0$ such that

$$
u_{\epsilon}(x-t \nu) \quad \text { and } \quad v_{\epsilon}(x-t \nu) \text { are nondecreasing for } t \in\left[0, t_{0}\right],
$$

$\nu \in \mathbb{R}^{N}$ with $|\nu|=1$, and $(\nu, n(x)) \geq \alpha$ and $x \in \partial \Omega$. Therefore we can find $\gamma, \delta$ such that for any $x \in\{z \in \bar{\Omega}: d(z, \partial \Omega)<\delta\}=\Omega_{\delta}$ there exists a measurable set $\Gamma_{x}$ with (i) $\operatorname{meas}\left(\Gamma_{x}\right) \geq \gamma$, (ii) $\Gamma_{x} \subset \Omega \backslash \bar{\Omega}_{\delta / 2}$, and (iii) $u_{\epsilon}(y) \geq u_{\epsilon}(x)$ and $v_{\epsilon}(y) \geq v_{\epsilon}(x)$ for any $y \in \Gamma_{x}$. Then for any $x \in \Omega_{\delta}$, we have

$$
\begin{aligned}
u_{\epsilon}(x) & \leq \frac{1}{\operatorname{meas}\left(\Gamma_{x}\right)} \int_{\Gamma_{x}} u_{\epsilon}(y) d y \leq \frac{1}{\gamma} \int_{\Omega_{\delta}} u_{\epsilon} \leq C\left(\Omega_{\delta}\right), \quad \text { and } \\
v_{\epsilon}(x) & \leq \frac{1}{\operatorname{meas}\left(\Gamma_{x}\right)} \int_{\Gamma_{x}} v_{\epsilon}(y) d y \leq \frac{1}{\gamma} \int_{\Omega_{\delta}} v_{\epsilon} \leq C\left(\Omega_{\delta}\right)
\end{aligned}
$$

Hence if $u_{\epsilon}\left(x_{\epsilon}\right) \rightarrow \infty$, this implies that $x_{\epsilon}$ will stay out of $\Omega_{\delta}$ a neighbordhood of the boundary. This proves the claim.

Let $x_{\epsilon} \rightarrow x_{0} \in \Omega$. We define a family of rescaled functions

$$
\begin{align*}
u_{\epsilon, \mu}(y) & =\mu^{\alpha_{\epsilon}} u_{\epsilon}\left(\mu^{1-\epsilon / 2} y+x_{\epsilon}\right)  \tag{2.8}\\
v_{\epsilon, \mu}(y) & =\mu^{\beta} v_{\epsilon}\left(\mu^{1-\epsilon / 2} y+x_{\epsilon}\right) \tag{2.9}
\end{align*}
$$

and find using the definitions of $\epsilon, \alpha_{\epsilon}$ and $\beta$, that

$$
\begin{align*}
-\Delta u_{\epsilon, \mu} & =v_{\epsilon, \mu}^{p} \mu^{\alpha_{\epsilon}+2-\epsilon-p \beta}=v_{\epsilon, \mu}^{p} \quad \text { in } \quad \Omega_{\epsilon}  \tag{2.10}\\
-\Delta v_{\epsilon, \mu} & =u_{\epsilon, \mu}^{q_{\epsilon}} \mu^{\beta+2-\epsilon-q_{\epsilon} \alpha_{\epsilon}}=u_{\epsilon, \mu}^{q_{\epsilon}} \quad \text { in } \quad \Omega_{\epsilon}  \tag{2.11}\\
u_{\epsilon, \mu} & =v_{\epsilon, \mu}=0 \quad \text { on } \quad \partial \Omega_{\epsilon} . \tag{2.12}
\end{align*}
$$

By equicontinuity and using Arzela-Ascoli, we have that

$$
\begin{equation*}
u_{\epsilon, \mu} \rightarrow U \quad \text { and } \quad v_{\epsilon, \mu} \rightarrow V \quad \text { as } \quad \epsilon \rightarrow 0 \tag{2.13}
\end{equation*}
$$

in $C^{2}(K)$ for any $K$ compact in $\mathbb{R}^{N}$, where $(U, V)$ satisfies (1.14)-(1.16). Now extending $u_{\epsilon, \mu}$ and $v_{\epsilon, \mu}$ by zero outside $\Omega_{\epsilon}$ and using (2.1), by the argument in [21] or [23], we have that $u_{\epsilon, \mu} \rightarrow \bar{U}$ strongly (up to a subsequence) in $W^{2, \frac{p+1}{p}}\left(\mathbb{R}^{N}\right)$. In the limit $\bar{U} \in L^{q+1}\left(\mathbb{R}^{N}\right)$ and $\bar{V}:=(-\Delta \bar{U})^{\frac{1}{p}} \in L^{p+1}\left(\mathbb{R}^{N}\right)$, and they satisfy (1.14)-(1.16).

Since $p \geq 1$, the solution $(\bar{U}, \bar{V})$ is unique and radially symmetric, see 5. In addition the radial solutions are unique [16, [23], so $\bar{U} \equiv U$ and $\bar{V} \equiv V$, consequently

$$
\begin{equation*}
\int_{\mathbb{R}^{N}}\left[u_{\epsilon, \mu}-U\right]^{q+1}(y) d y \rightarrow 0 \quad \int_{\mathbb{R}^{N}}\left[v_{\epsilon, \mu}-V\right]^{p+1}(y) d y \rightarrow 0 . \tag{2.14}
\end{equation*}
$$

Lemma 2.2. There exists $\delta>0$ such that

$$
\delta \leq \mu^{\epsilon} \leq 1
$$

Proof. Since $\mu \rightarrow 0$, we have $\mu^{\epsilon} \leq 1$. By (2.14), we get $\int_{B_{1}} u_{\epsilon, \mu}^{q_{\epsilon}+1} d x \geq M$, but

$$
\begin{equation*}
M \leq \int_{B_{1}} u_{\epsilon, \mu}^{q_{\epsilon}+1} d x=\mu^{\epsilon N / 2} \int_{\left|y-x_{\epsilon}\right| \leq \mu^{1-\epsilon / 2}} u_{\epsilon}^{q_{\epsilon}+1}(y) d y \leq \mu^{\epsilon N / 2} \int_{\Omega} u_{\epsilon}^{q_{\epsilon}+1}(y) d y \tag{2.15}
\end{equation*}
$$

Using the convergence (2.1), we obtain the result.
Lemma 2.3. There exists $K>0$ such that the solution $\left(u_{\epsilon, \mu}, v_{\epsilon, \mu}\right)$ satisfies

$$
\begin{equation*}
u_{\epsilon, \mu}(y) \leq K U(y) \quad v_{\epsilon, \mu}(y) \leq K V(y) \quad \forall y \in \mathbb{R}^{N} \tag{2.16}
\end{equation*}
$$

We prove this lemma in section 2.3,
Lemma 2.4. There exists a constant $C>0$ such that

$$
\epsilon \leq C \mu^{N-2} h(\mu) \quad \text { with } \quad h(\mu)= \begin{cases}1 & \text { for } \quad p>N /(N-2)  \tag{2.17}\\ |\log (\mu)| & \text { for } \quad p=N /(N-2) \\ \mu^{(p(N-2)-N)} & \text { for } \quad p<N /(N-2)\end{cases}
$$

Proof. We will establish the following

$$
\int_{\partial \Omega} \frac{\partial u_{\epsilon}}{\partial n} \frac{\partial v_{\epsilon}}{\partial n}(n, x) d x \leq C \mu^{N-2} h(\mu)
$$

and from here the result follows applying (2.7). We claim that

$$
\left|\frac{\partial u_{\epsilon}}{\partial n}\right| \leq C \mu^{\alpha_{\epsilon}} \quad\left|\frac{\partial v_{\epsilon}}{\partial n}\right| \leq C \mu^{\beta} h(\mu)
$$

In the following $M$ is a positive constant that can vary from line to line and we shall use systematically Lemma 2.2 .

For $p>N /(N-2)$, using that $-p \beta+N=\beta$, we have

$$
\int_{\Omega} v_{\epsilon}^{p}(x) d x \leq M \mu^{-p \beta+N(1-\epsilon / 2)} \int_{\mathbb{R}^{N}} V^{p}(y) d y \leq M \mu^{\beta}
$$

and by (2.16) there exists $M>0$ such that

$$
\begin{equation*}
v_{\epsilon}^{p}(x) \leq M \frac{\mu^{\beta+p(N-2)-N-p(N-2) \epsilon / 2}}{\left|x-x_{0}\right|^{p(N-2)}} \tag{2.18}
\end{equation*}
$$

for $x \neq x_{0}$. Using that $\beta<\beta+p(N-2)-N$, by Lemma 5.1 we find $\left|\frac{\partial v_{\epsilon}}{\partial n}\right| \leq C \mu^{\beta}$. For $u_{\epsilon}$, using that $-q_{\epsilon} \alpha_{\epsilon}+N=\alpha_{\epsilon}$,

$$
\int_{\Omega} u_{\epsilon}^{q_{\epsilon}} d x \leq M \mu^{-q_{\epsilon} \alpha_{\epsilon}+N(1-\epsilon / 2)} \int_{\mathbb{R}^{N}} U^{q}(y) d y \leq M \mu^{\alpha_{\epsilon}}
$$

and by (2.16) there exist $M>0$ such

$$
\begin{equation*}
u_{\epsilon}^{q_{\epsilon}}(x) \leq M \frac{\mu^{-q_{\epsilon} \alpha_{\epsilon}+q_{\epsilon}(N-2)-q_{\epsilon}(N-2) \epsilon / 2}}{\left|x-x_{0}\right|_{\epsilon \epsilon}(N-2)} \tag{2.19}
\end{equation*}
$$

for $x \neq x_{0}$. Using that $\alpha_{\epsilon}<\alpha_{\epsilon}-N+q_{\epsilon}(N-2)$, by Lemma 5.1] we obtain $\left|\frac{\partial u_{\epsilon}}{\partial n}\right| \leq C \mu^{\alpha_{\epsilon}}$.
For $p<N /(N-2)$, we have

$$
\begin{align*}
& \int_{\Omega} v_{\epsilon}^{p} d x \leq M \mu^{-p \beta+p(N-2)(1-\epsilon / 2)} \lim _{\mu \rightarrow 0} \frac{1}{\mu^{(p(N-2)-N)(1-\epsilon / 2)}} \int_{B \frac{1}{\mu^{1-\epsilon / 2}}\left(x_{\epsilon}\right)} V^{p}(y) d y  \tag{2.20}\\
& \leq M \mu^{\beta+(p(N-2)-N)} \tag{2.21}
\end{align*}
$$

and for $x \neq x_{0}$, we find (2.18) for $v_{\epsilon}$ and for $u_{\epsilon}$ we have

$$
\int_{\Omega} u_{\epsilon}^{q_{\epsilon}} \leq M \mu^{-q_{\epsilon} \alpha_{\epsilon}+N(1-\epsilon / 2)} \int_{\mathbb{R}^{N}} U^{q}(y) d y \leq M \mu^{\alpha_{\epsilon}}
$$

and by (2.16) there exist $M>0$ such that

$$
\begin{equation*}
u_{\epsilon}^{q_{e}}(x) \leq M \frac{\mu^{-q_{\epsilon} \alpha_{\epsilon}+q_{\epsilon}(p(N-2)-2)-q_{\epsilon}(p(N-2)-2) \epsilon / 2}}{\left|x-x_{0}\right|^{q_{\epsilon}(p(N-2)-2)}} \tag{2.22}
\end{equation*}
$$

for $x \neq x_{0}$. From these estimates we prove the claim applying Lemma 5.1 and noting that $\alpha_{\epsilon}<\alpha_{\epsilon}-N+q_{\epsilon}(p(N-2)-2)+(p+1) \epsilon / \alpha_{\epsilon}$. For the case $p=N /(N-2)$, we proceed as before noting that

$$
\int_{\Omega} v_{\epsilon}^{p} d x \leq M \mu^{-p \beta+N(1-\epsilon / 2)}|\log (\mu)| \lim _{\mu \rightarrow 0} \frac{1}{|\log (\mu)|} \int_{\frac{B}{\mu^{1-\epsilon / 2}}\left(x_{\epsilon}\right)} V^{p}(y) d y \leq M|\log (\mu)| \mu^{\beta}
$$

and for $x \neq x_{0}$ we have (2.18). Similarly to (2.22), we obtain that for $x \neq x_{0}$, there exist $M>0$ such that

$$
\begin{equation*}
u_{\epsilon}^{q_{\epsilon}}(x) \leq M \frac{\mu^{-q_{\epsilon} \alpha_{\epsilon}+q_{\epsilon}(N-2)-q_{\epsilon}(N-2) \epsilon / 2}}{\left|x-x_{0}\right|_{\epsilon}(N-2)} \log \left(\left|x-x_{0}\right| \mu^{-1+\epsilon / 2}\right)^{q_{\epsilon}} . \tag{2.23}
\end{equation*}
$$

Using this and proceeding and before we prove the claim and the lemma follows.
Lemma 2.5.

$$
\left|\mu^{\epsilon}-1\right|=O\left(\mu^{N-2} h(\mu) \log \mu\right)
$$

Proof. By the theorem of the mean $\left|\mu^{\epsilon}-1\right|=\left|\mu^{s \epsilon} \epsilon \log \mu\right|$ for some $s \in(0,1)$ and therefore (2.17) gives the result.

## 3. Proof of Theorem 1.2 and 1.3

Proof of Theorem 1.3. We start by proving the case $p>\frac{N}{N-2}$. We have

$$
\begin{align*}
-\Delta\left(\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}} u_{\epsilon}\right) & =\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}} v_{\epsilon}^{p} \quad \text { in } \quad \Omega  \tag{3.1}\\
-\Delta\left(\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} v_{\epsilon}\right) & =\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} u_{\epsilon}^{q_{\epsilon}} \quad \text { in } \Omega  \tag{3.2}\\
u_{\epsilon} & =v_{\epsilon}=0 \quad \text { on } \partial \Omega . \tag{3.3}
\end{align*}
$$

We integrate the right hand side of (3.1)

$$
\int_{\Omega}\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}} v_{\epsilon}^{p} d x=\mu^{-(p+1) \beta+N+N \epsilon / 2} \int_{\Omega_{\epsilon}} v_{\epsilon, \mu}^{p}(y) d y
$$

But $N-(p+1) \beta=0$, so using (2.16) by dominated convergence and Lemma 2.5, we get

$$
\lim _{\epsilon \rightarrow 0} \int_{\Omega}\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}} v_{\epsilon}^{p} d x=\int_{\mathbb{R}^{N}} V^{p}(y) d y=\|V\|_{L^{p}\left(\mathbb{R}^{N}\right)}<\infty .
$$

Similarly, now using

$$
\begin{equation*}
\int_{\Omega}\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} u_{\epsilon}^{q_{\epsilon}} d x=\mu^{-\left(q_{\epsilon}+1\right) \alpha_{\epsilon}+N+N \epsilon / 2} \int_{\Omega_{\epsilon}} u_{\epsilon, \mu}^{q_{\epsilon}} d x \rightarrow\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}<\infty \tag{3.4}
\end{equation*}
$$

as $\epsilon \rightarrow 0$. Also using the bound (2.16), we find

$$
\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}} v_{\epsilon}^{p}(x) \leq \frac{M \mu^{-(p+1) \beta+p(N-2)-p(N-2) \epsilon / 2}}{\left|x-x_{0}\right|^{p(N-2)}}
$$

for $x \neq x_{0}$ and some $M>0$. But $-(p+1) \beta+p(N-2)>0$ and Lemma 2.2 then $\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}} v_{\epsilon}^{p}(x) \rightarrow 0$ for $x \neq x_{0}$. Also we have

$$
\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} u_{\epsilon}^{q_{\epsilon}}(x) \leq \frac{M \mu^{-\left(q_{\epsilon}+1\right) \alpha_{\epsilon}+q_{\epsilon}(N-2)-q_{\epsilon}(N-2) \epsilon / 2}}{\left|x-x_{0}\right|_{\epsilon}(N-2)} .
$$

for $x \neq x_{0}$ and some $M>0$. But $-\left(q_{\epsilon}+1\right) \alpha_{\epsilon}+q_{\epsilon}(N-2)>0$ and Lemma [2.2 then $\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} u_{\epsilon}^{q_{\epsilon}}(x) \rightarrow 0$ for $x \neq x_{0}$.

From here we have

$$
-\Delta\left(\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}} u_{\epsilon}\right) \rightarrow\|V\|_{L^{p}\left(\mathbb{R}^{N}\right)}^{p} \delta_{x=x_{0}} \quad \text { and } \quad-\Delta\left(\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} v_{\epsilon}\right) \rightarrow\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{q} \delta_{x=x_{0}}
$$

in the sense of distributions in $\Omega$, as $\epsilon \rightarrow 0$. Let $\omega$ be any neighborhood of $\partial \Omega$ not containing $x_{0}$. By regularity theory, see Lemma 5.1. we find

$$
\left\|\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}} u_{\epsilon}\right\|_{C^{1, \alpha}(w)} \leq C\left[\| \| u_{\epsilon}\left\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}} v_{\epsilon}^{p}\right\|_{L^{1}(\Omega)}+\| \| u_{\epsilon}\left\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}} v_{\epsilon}^{p}\right\|_{L^{\infty}(w)}\right]
$$

and a similar bound for $\left\|\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} v_{\epsilon}\right\|_{C^{1, \alpha}(w)}$. Consequently

$$
\begin{equation*}
\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}} u_{\epsilon} \rightarrow\|V\|_{L^{p}\left(\mathbb{R}^{N}\right)}^{p} G \quad \text { in } \quad C^{1, \alpha}(w) \quad \text { as } \quad \epsilon \rightarrow 0 . \tag{3.5}
\end{equation*}
$$

and

$$
\begin{equation*}
\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} v_{\epsilon} \rightarrow\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{q} G \quad \text { in } \quad C^{1, \alpha}(w) \quad \text { as } \quad \epsilon \rightarrow 0 \tag{3.6}
\end{equation*}
$$

For the case $p<N /(N-2)$, we proceed as before and we have (3.4) and the bound

$$
\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} u_{\epsilon}^{q_{\epsilon}}(x) \leq \frac{M \mu^{-\left(q_{\epsilon}+1\right) \alpha_{\epsilon}+q_{\epsilon}(p(N-2)-2)-q_{\epsilon}(p(N-2)-2) \epsilon / 2}}{\left|x-x_{0}\right|^{q_{\epsilon}(p(N-2)-2)}} .
$$

for $x \neq x_{0}$ and some $M>0$. Using that $-\left(q_{\epsilon}+1\right) \alpha_{\epsilon}+q(p(N-2)-2)=2(p+1)>0$ and Lemma 2.2, we get $\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}} u_{\epsilon}^{q_{\epsilon}}(x) \rightarrow 0$ for $x \neq x_{0}$ and hence

$$
\begin{equation*}
\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} v_{\epsilon} \rightarrow\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{q} G \quad \text { in } \quad C^{1, \alpha}(w) \quad \text { as } \quad \epsilon \rightarrow 0 . \tag{3.7}
\end{equation*}
$$

Now we claim that

$$
\begin{equation*}
\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{1}{\alpha}(\beta+p(N-2)-N)} u_{\epsilon} \rightarrow\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{p q} \tilde{G} \quad \text { in } \quad C^{1, \alpha}(w) \quad \text { as } \quad \epsilon \rightarrow 0 . \tag{3.8}
\end{equation*}
$$

We have

$$
-\Delta\left(\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{1}{\alpha}(\beta+p(N-2)-N)} u_{\epsilon}\right)=\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{1}{\alpha}(\beta+p(N-2)-N)} v_{\epsilon}^{p}=\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{p} v_{\epsilon}^{p} .
$$

Since the last term converges to $\left(\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{q} G\right)^{p}$ in $C^{1, \alpha}(\omega)$ as $\epsilon \rightarrow 0$ and $p \geq 1$, we have

$$
\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{1}{\alpha}(\beta+p(N-2)-N)} u_{\epsilon} \rightarrow\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{p q} \tilde{G} \quad \text { in } \quad C^{3, \alpha}(w) \quad \text { as } \quad \epsilon \rightarrow 0 .
$$

For the remaining case $p=N /(N-2)$, we have as $\epsilon \rightarrow 0$, the convergence

$$
\int_{\Omega} \frac{\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}}}{\left|\log \left(\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}\right)\right|} v_{\epsilon}^{p} d x=\frac{\mu^{-(p+1) \beta+N+N \epsilon / 2}}{\alpha_{\epsilon}|\log (\mu)|} \int_{\Omega_{\epsilon}} v_{\epsilon, \mu}^{p} d y \rightarrow \frac{1}{\alpha} \lim _{r \rightarrow \infty} V(r)^{\frac{N}{N-2}} r^{N}=\frac{a^{\frac{N}{N-2}}}{\alpha} .
$$

and the pointwise bound for $x \neq x_{0}$

$$
\frac{\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}}}{\left|\log \left(\left\|u_{\epsilon}\right\|^{\frac{\beta}{\alpha}}\right)\right|} v_{\epsilon}^{p}(x) \leq \frac{M \mu^{-p(N-2) \epsilon / 2}}{\log (\mu)\left|x-x_{0}\right|^{p(N-2)}} .
$$

By Lemma 2.2, $\frac{\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}}}{\left|\log \left(\left\|u_{\epsilon}\right\| \frac{\beta}{\alpha}\right)\right|} v_{\epsilon}^{p}(x) \rightarrow 0$ for $x \neq x_{0}$. Writing

$$
-\Delta\left(\frac{\left\|u_{\epsilon}\right\|_{L^{\infty}}^{\frac{\beta}{\alpha}}}{\left|\log \left(\left\|u_{\epsilon}\right\|^{\frac{\beta}{\alpha}}\right)\right|} u_{\epsilon}\right)=\frac{\left\|u_{\epsilon}\right\|_{L^{\infty}}^{\frac{\beta}{\alpha}}}{\left|\log \left(\left\|u_{\epsilon}\right\|^{\frac{\beta}{\alpha}}\right)\right|} v_{\epsilon}^{p}
$$

we observe that the last term converges to $\delta_{x=x_{0}}$. By Lemma 5.1, we have

$$
\frac{\left\|u_{\epsilon}\right\|_{L^{\infty}}^{\frac{\beta}{\alpha}}}{\left|\log \left(\left\|u_{\epsilon}\right\|^{\frac{\beta}{\alpha}}\right)\right|} u_{\epsilon} \rightarrow \frac{a^{\frac{N}{N-2}}}{\alpha} G \quad \text { in } \quad C^{1, \alpha}(w) \quad \text { as } \quad \epsilon \rightarrow 0
$$

and clearly we have (3.6) using (2.23). This completes the proof of the theorem.

Proof of Theorem 1.2. For $p>N /(N-2)$ we have

$$
\epsilon\left\|u_{\epsilon}\right\|^{\frac{N-2}{\alpha}} \int_{\Omega} u_{\epsilon}^{q_{\epsilon}+1} d x=\int_{\partial \Omega}\left(\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{\beta}{\alpha}} \nabla u_{\epsilon}, n\right)\left(\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} \nabla v_{\epsilon}, n\right)(n, x-y) d s
$$

By (3.5) and (3.6),
$\lim _{\epsilon \rightarrow 0} \epsilon\left\|u_{\epsilon}\right\|^{\frac{N-2}{\alpha}} \int_{\Omega} u_{\epsilon}^{q_{\epsilon}+1} d x=\|V\|_{L^{p}\left(\mathbb{R}^{N}\right)}^{p}\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{q} \int_{\partial \Omega} \frac{\partial G\left(x, x_{0}\right)}{\partial n} \frac{\partial G\left(x, x_{0}\right)}{\partial n}\left(n, x-x_{0}\right) d s$.
Also for the case $p<N /(N-2)$, using

$$
\begin{aligned}
& \epsilon\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{1}{\alpha}(p(N-2)-2)} \int_{\Omega} u_{\epsilon}^{q_{\epsilon}+1} d x \\
& \quad=\int_{\partial \Omega}\left(\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{1}{\alpha}(\beta+p(N-2)-N)} \nabla u_{\epsilon}, n\right)\left(\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)} \nabla v_{\epsilon}, n\right)(n, x-y) d s
\end{aligned}
$$

and (3.8) and (3.7), we get

$$
\begin{aligned}
& \lim _{\epsilon \rightarrow 0} \epsilon\left\|u_{\epsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{1}{\alpha}(p(N-2)-2)} \int_{\Omega} u_{\epsilon}^{q_{\epsilon}+1} d x \\
& \quad=\|U\|_{L^{q}\left(\mathbb{R}^{N}\right)}^{q(p+1)} \int_{\partial \Omega} \frac{\partial \tilde{G}\left(x, x_{0}\right)}{\partial n} \frac{\partial G\left(x, x_{0}\right)}{\partial n}\left(n, x-x_{0}\right) d s .
\end{aligned}
$$

The case $p=N /(N-2)$ is analogous.
The proof of the theorems follows from the next lemma.
Lemma 3.1. We have the following identities

$$
\text { i) } \int_{\partial \Omega} \frac{\partial G\left(x, x_{0}\right)}{\partial n} \frac{\partial G\left(x, x_{0}\right)}{\partial n}\left(n, x-x_{0}\right) d s=-(N-2) g\left(x_{0}, x_{0}\right)
$$

and

$$
\text { ii) } \int_{\partial \Omega} \frac{\partial \tilde{G}\left(x, x_{0}\right)}{\partial n} \frac{\partial G\left(x, x_{0}\right)}{\partial n}\left(n,, x-x_{0}\right) d s=-\frac{N}{q+1} \tilde{g}\left(x_{0}, x_{0}\right)
$$

Proof. i) was proven in [3], see also [13]. To prove ii) we follow a similar procedure. From [18, 22], for any $y \in \mathbb{R}^{N}$, we have the following identity

$$
\begin{aligned}
& \int_{\Omega^{\prime}} \Delta u(x-y, \nabla v)+\Delta v(x-y, \nabla u)-(N-2)(\nabla u, \nabla v) d x= \\
& \int_{\partial \Omega^{\prime}} \frac{\partial u}{\partial n}(x-y, \nabla v)+\frac{\partial v}{\partial n}(x-y, \nabla u)-(\nabla u, \nabla v)(x-y, n) d s
\end{aligned}
$$

where $\Omega^{\prime}=\Omega \backslash B_{r}$ with $r>0$. For a system $-\Delta v=0$ and $-\Delta u=v^{p}$, in $\Omega^{\prime}$, the identity takes the form

$$
\begin{array}{r}
\int_{\Omega^{\prime}} \frac{N}{p+1} v^{p+1}-\bar{a} v^{p+1} d x=\int_{\partial \Omega^{\prime}} \frac{1}{p+1} v^{p+1}(x-y, n) d s \\
+\int_{\partial \Omega^{\prime}} \frac{\partial u}{\partial n}[(x-y, \nabla v)+\bar{a} v]+\frac{\partial v}{\partial n}[(x-y, \nabla u)+\bar{b} u]-(\nabla u, \nabla v)(x-y, n) d s \tag{3.9}
\end{array}
$$

with $\bar{a}+\bar{b}=N-2$. Let $y=0$, choose $\bar{a}=N /(p+1)$ and take $v=G(x, 0)$ and $u=\tilde{G}(x, 0)$. Using that $u=v=0$ on $\partial \Omega$, and so $\nabla u=(\nabla u, n) n$ and $\nabla v=(\nabla v, n) n$ on $\partial \Omega$,, we obtain

$$
\begin{aligned}
\int_{\partial \Omega} \frac{\partial \tilde{G}}{\partial n} \frac{\partial \tilde{G}}{\partial n}(x, n) d s= & \int_{\partial B_{r}} \frac{1}{p+1} G^{p+1}(x, n)+\frac{\partial \tilde{G}}{\partial n}\left[(x, \nabla G)+\frac{N}{p+1} G\right] d s \\
& +\int_{\partial B_{r}} \frac{\partial G}{\partial n}\left[(x, \nabla \tilde{G})+\frac{N}{q+1} \tilde{G}\right]-(\nabla \tilde{G}, \nabla G)(x, n) d s
\end{aligned}
$$

Let $k=p(N-2)$ and $\Gamma=\sigma_{N}(N-2)$. For $|x|=r$, we have

$$
\begin{gathered}
\nabla \tilde{G}=-\frac{1}{\Gamma^{p}(N-k)}|x|^{-k} x+\nabla \tilde{g}, \quad \nabla G=-\frac{1}{\sigma_{N}}|x|^{-N} x+\nabla g, \\
\frac{\partial \tilde{G}}{\partial n}=-\frac{1}{\Gamma^{p}(N-k)}|x|^{1-k}+(\nabla \tilde{g}, n), \quad \frac{\partial G}{\partial n}=-\frac{1}{\sigma_{N}}|x|^{1-N}+(\nabla g, n) \\
(x, \nabla \tilde{G})+\frac{N}{q+1} \tilde{G}=\left(\frac{N}{(q+1)(k-2)}-1\right) \frac{1}{\Gamma^{p}(N-k)}|x|^{2-k}+(x, \nabla \tilde{g})+\frac{N}{q+1} \tilde{g} \\
(x, \nabla G)+\frac{N}{p+1} G=\left(\frac{N}{p+1}-(N-2)\right) \frac{1}{\Gamma}|x|^{2-N}+(x, \nabla g)+\frac{N}{p+1} g \\
(\nabla \tilde{G}, \nabla G)=\frac{|x|^{-k-N+2}}{\sigma_{N} \Gamma^{p}(N-k)}-\frac{(\nabla g, x)}{\Gamma^{p}(N-k)}|x|^{(2-N) p}-\frac{(\nabla \tilde{g}, x)}{\sigma_{N}}|x|^{-N}+(\nabla \tilde{g}, \nabla g)
\end{gathered}
$$

and

$$
\frac{1}{p+1} G^{p+1}=\frac{1}{p+1}\left[\frac{1}{\Gamma^{p}}|x|^{-k}-\Delta \tilde{g}\right]\left[\frac{1}{\Gamma}|x|^{2-N}+g\right]
$$

From here, we check that terms with $|x|^{3-N-k}$ cancel out others integral tends to 0 since the integrand are $o\left(|x|^{1-N}\right)$ and only remain one term of order $|x|^{1-N}$, giving

$$
\int_{\partial \Omega} \frac{\partial \tilde{G}}{\partial n} \frac{\partial G}{\partial n}(x, n) d s=-\lim _{r \rightarrow 0} \frac{1}{\sigma_{N} r^{N-1}} \int_{\partial B_{r}} \frac{N}{q+1} \tilde{g} d s=-\frac{N}{q+1} \tilde{g}(0,0)
$$

Proof of Theorem [1.1. a) The part ii) follows from Theorem 5.1

$$
\left\|\left|\Delta u_{\epsilon}\right|^{\frac{1}{p}}\right\|_{C^{1, \alpha}(\omega)} \leq\left\|u_{\epsilon}^{q_{\epsilon}}\right\|_{L^{1}(\Omega)}+\left\|u_{\epsilon}^{q_{\epsilon}}\right\|_{L^{\infty}(\omega)}
$$

and estimates (2.19), (2.22), and (2.23). Part i) follows from

$$
\left\|u_{\epsilon}\right\|_{C^{1, \alpha}(\omega)} \leq\left\|v_{\epsilon}^{p}\right\|_{L^{1}(\Omega)}+\left\|v_{\epsilon}^{p}\right\|_{L^{\infty}(\omega)} .
$$

and estimate (2.18). Finally iii) follows combining ii) with the convergence

$$
\int_{\mathbb{R}^{N}}\left|\Delta u_{\epsilon}\right|^{\frac{p+1}{p}} d x=\int_{\mathbb{R}^{N}} v_{\epsilon}^{p+1} d x \rightarrow\|V\|_{L^{p+1}\left(\mathbb{R}^{N}\right)}^{p+1}
$$

as $\epsilon \rightarrow 0$. This completes part a).
For part b), note that from (2.7), we have the vectorial equality $\int_{\partial \Omega}\left(\nabla u_{\epsilon}, \nabla v_{\epsilon}\right) n d s=$ 0 . In the limit for $p \geq N /(N-2)$, we get

$$
\begin{equation*}
\int_{\partial \Omega}\left(\nabla G\left(x, x_{0}\right), \nabla G\left(x, x_{0}\right)\right) n d s=0 \tag{3.10}
\end{equation*}
$$

and similarly for $p<N /(N-2)$, we obtain

$$
\begin{equation*}
\int_{\partial \Omega}\left(\nabla \tilde{G}\left(x, x_{0}\right), \nabla G\left(x, x_{0}\right)\right) n d s=0 \tag{3.11}
\end{equation*}
$$

But we have the following result.
Lemma 3.2. For every $x_{0} \in \Omega$

$$
\begin{equation*}
\int_{\partial \Omega}\left(\nabla G\left(x, x_{0}\right), n\right)\left(\nabla G\left(x, x_{0}\right), n\right) n d s=-\nabla \phi\left(x_{0}\right) \tag{3.12}
\end{equation*}
$$

and

$$
\begin{equation*}
\int_{\partial \Omega}\left(\nabla \tilde{G}\left(x, x_{0}\right), n\right)\left(\nabla\left(\Delta \tilde{G}\left(x, x_{0}\right)\right)^{1 / p}, n\right) n d s=-\nabla \tilde{\phi}\left(x_{0}\right) . \tag{3.13}
\end{equation*}
$$

Hence combining (3.10) with (3.12), and (3.11) with (3.13), we complete the proof of part b) and the theorem is proven.

Proof of the Lemma. Equality (3.12) was proved in [3] and [13]. To prove (3.13), by (3.9) we have

$$
\int_{\partial \Omega} \frac{\partial \tilde{G}}{\partial n} \frac{\partial G}{\partial n} n d s=\int_{\partial B_{r}}\left\{\frac{1}{p+1} G^{p+1} n+\frac{\partial \tilde{G}}{\partial n} \nabla G+\frac{\partial G}{\partial n} \nabla \tilde{G}-(\nabla \tilde{G}, \nabla G) n\right\} d s
$$

Using $\int_{\partial B_{r}} n=0$, we get

$$
\begin{align*}
\int_{\partial \Omega} \frac{\partial \tilde{G}}{\partial n} \frac{\partial G}{\partial n} n d s= & \frac{1}{(p+1) r^{N-1}} \int_{\partial B_{r}}\left\{\frac{1}{\Gamma^{p}} r^{N-k-1} g-\Delta \tilde{g} \frac{1}{\Gamma} r-\Delta \tilde{g} g r^{N-1}\right\} n d s \\
+ & \frac{1}{r^{N-1}} \int_{\partial B_{r}}\{(\nabla \tilde{g}, n) \nabla g+(\nabla g, n) \nabla \tilde{g}-(\nabla \tilde{g}, \nabla g) n\} r^{N-1} d s \\
& -\frac{1}{r^{N-1}} \int_{\partial B_{r}}\left\{\frac{1}{\sigma_{N}} \nabla \tilde{g}+\frac{r^{N-k}}{\Gamma^{p}(N-k)} \nabla g\right\} d s \tag{3.14}
\end{align*}
$$

We use the regular $\hat{g}(x, 0)$ instead of $\tilde{g}(x, 0)$. Thus

$$
\begin{align*}
\nabla \hat{g}(x, 0) & =\nabla \tilde{g}(x, 0)+\frac{p g(0,0)}{\Gamma^{p-1}(2 N-k-2)}|x|^{N-k-2} x  \tag{3.15}\\
\Delta \hat{g}(x, 0) & =\Delta \tilde{g}(x, 0)+\frac{p g(0,0)}{\Gamma^{p-1}}|x|^{N-k-2} \tag{3.16}
\end{align*}
$$

But $g(x, 0)=g(0,0)+(\nabla g(0,0), x)+o\left(|x|^{2}\right)$ and

$$
\int_{\partial B_{r}} r^{-k} g(x, 0) n d s=\int_{\partial B_{1}} r^{N-k-1} g(0,0) n d s+\int_{\partial B_{1}} r^{N-k}(\nabla g(0,0), y) n d s+o\left(r^{N-k+1}\right)
$$

where $y=x / r$. Clearly the first integral in the r.h.s is zero and the other terms tends to zero as $r \rightarrow 0$. Hence

$$
\begin{equation*}
\lim _{r \rightarrow 0} \frac{1}{r^{N-1}} \int_{\partial B_{r}} r^{N-k-1} g(x, 0) n d s=0 . \tag{3.17}
\end{equation*}
$$

We replace (3.15) and (3.16) in (3.14), to obtain an identity without $\tilde{g}$. Using the limit (3.17) and that $\hat{g}$ and $g$ are regular, we obtain

$$
\int_{\partial \Omega} \frac{\partial \tilde{G}}{\partial n} \frac{\partial G}{\partial n} n d s=\lim _{r \rightarrow 0} \frac{1}{r^{N-1}} \int_{\partial B_{r}} \frac{1}{\sigma_{N}} \nabla \hat{g} d s=\nabla \hat{g}(0,0)=\nabla \tilde{\phi}(0)
$$

where the last equality follows by observation after Theorem 1.1

## 4. Proof of Lemma 2.3

Let us recall the problem (2.10) $-(2.12)$,

$$
\begin{align*}
-\Delta u_{\epsilon, \mu} & =v_{\epsilon, \mu}^{p} \quad \text { in } \Omega_{\epsilon}  \tag{4.1}\\
-\Delta v_{\epsilon, \mu} & =u_{\epsilon, \mu}^{q_{\epsilon}} \text { in } \Omega_{\epsilon}  \tag{4.2}\\
u_{\epsilon, \mu} & =v_{\epsilon, \mu}=0 \quad \text { on } \partial \Omega_{\epsilon} \tag{4.3}
\end{align*}
$$

where $\Omega_{\epsilon}=\left(\Omega-x_{\epsilon}\right) / \mu^{1-\epsilon / 2}$. Let $\bar{R}>0$. We define $\sigma(p):=2+N-p(N-2)$, and the scalar function

$$
J(|y|):=\left\{\begin{array}{l}
1 \quad \text { if } \quad \sigma(p)<2 \\
|\log (|y| / \bar{R})| \quad \text { if } \quad \sigma(p)=2 \\
|y|^{2-\sigma(p)} \quad \text { if } \quad \sigma(p)>2
\end{array}\right.
$$

Note that $\sigma(p) \in[0, N)$ for $p \in(2 /(N-2),(N+2) /(N-2)]$ and $\sigma(q) \leq 0$. We consider the transformations

$$
z_{\epsilon}(y)=|y|^{2-N} v_{\epsilon, \mu}\left(\frac{y}{|y|^{2}}\right) \quad \text { and } \quad w_{\epsilon}(y)=\frac{|y|^{2-N}}{J(|y|)} u_{\epsilon, \mu}\left(\frac{y}{|y|^{2}}\right)
$$

in $\Omega_{\epsilon}^{*}$, the image of $\Omega_{\epsilon}$ under $x \mapsto x /|x|^{2}$.
The next lemma is equivalent to Lemma 2.3, using the asymptotic behaviour (1.17).
Lemma 4.1. Let $\left(w_{\epsilon}, z_{\epsilon}\right)$ solving

$$
\begin{align*}
-\Delta J(|y|) w_{\epsilon} & =|y|^{-\sigma(p)} z_{\epsilon}^{p} \quad \text { in } \quad \Omega_{\epsilon}^{*}  \tag{4.4}\\
-\Delta z_{\epsilon} & =|y|^{-\sigma(q)+\left(q_{\epsilon}-q\right)(N-2)}\left[J(|y|) w_{\epsilon}\right]^{q_{\epsilon}} \text { in } \quad \Omega_{\epsilon}^{*}  \tag{4.5}\\
w_{\epsilon}=z_{\epsilon} & =0 \quad \text { on } \quad \partial \Omega_{\epsilon}^{*} . \tag{4.6}
\end{align*}
$$

Then for any fixed $R \in(0, \bar{R})$, we have

$$
\left\|w_{\epsilon}\right\|_{L^{\infty}\left(\Omega_{\epsilon}^{R}\right)}+\left\|z_{\epsilon}\right\|_{L^{\infty}\left(\Omega_{\epsilon}^{R}\right)} \leq C
$$

where $\Omega_{\epsilon}^{R}=\Omega_{\epsilon}^{*} \cap B_{R}$, and $C=C(R)$ independent of $\epsilon>0$ provided $\epsilon$ is sufficiently small.

Proof. Given $R>0$, let $w_{0}$ and $z_{0}$ be solutions of

$$
\Delta J(|y|) w_{0}=0 \quad \text { in } \quad \Omega_{\epsilon}^{R} \quad \text { and } \quad w_{0}=0, \text { on } \quad \partial \Omega_{\epsilon}^{*} \quad w_{0}=w_{\epsilon} \quad \text { on } \quad \partial B_{R},
$$

and

$$
\Delta z_{0}=0 \quad \text { in } \quad \Omega_{\epsilon}^{R} \quad \text { and } \quad z_{0}=0, \text { on } \quad \partial \Omega_{\epsilon}^{*} \quad z_{0}=z_{\epsilon} \quad \text { on } \quad \partial B_{R} .
$$

By the convergence in compact sets of $w_{\epsilon}$ and $z_{\epsilon}$, see (2.13), we have $\left|z_{\epsilon}\right|+\left|\nabla z_{\epsilon}\right|+$ $\left|w_{\epsilon}\right|+\left|\nabla w_{\epsilon}\right| \leq C$ in $|y|=R$ for $C$ independent of $\epsilon$. Therefore by the maximum principle, we get

$$
\left|J w_{0}\right|+\left|\nabla\left(J w_{0}\right)\right|+\left|z_{0}\right|+\left|\nabla z_{0}\right| \leq C \quad \text { in } \quad \Omega_{\epsilon}^{R} .
$$

Define $\tilde{w}=w_{\epsilon}-w_{0}$ and $\tilde{z}=z_{\epsilon}-z_{0}$. We now write

$$
\begin{align*}
-\Delta J(|y|) \tilde{w} & =a(y) z_{\epsilon} \quad \text { in } \quad \Omega_{\epsilon}^{R}  \tag{4.7}\\
-\Delta \tilde{z} & =b(y) J(|y|) w_{\epsilon} \text { in } \Omega_{\epsilon}^{R}  \tag{4.8}\\
\tilde{w} & =\tilde{z}=0 \quad \text { on } \partial \Omega_{\epsilon}^{R} \tag{4.9}
\end{align*}
$$

where $a(y)=|y|^{-\sigma(p)} z_{\epsilon}^{p-1}$ and $b(y)=|y|^{-\sigma(q)+\left(q_{\epsilon}-q\right)(N-2)}\left[J(|y|) w_{\epsilon}\right]^{q_{\epsilon}-1}$. Clearly by the maximum principle $\tilde{w} \geq 0$ and $\tilde{z} \geq 0$.

Let $P(y)=a(y)$ and

$$
Q(y)=\left\{\begin{array}{l}
\frac{1}{M} b(y) \text { for } y \in B_{R} \backslash \bar{B}_{r} \\
b(y) \text { for } B_{r}
\end{array}\right.
$$

where $r \in(0, R)$ and $M>1$ both independent of $\epsilon$ and to be determined later. Then

$$
b(y) J(|y|) w_{\epsilon}=Q(y) J(|y|) w_{\epsilon}+f(y)
$$

where

$$
f(y)=(b(y)-Q(y)) J(|y|) w_{\epsilon}=\left\{\begin{array}{l}
0 \text { for } y \in \Omega_{\epsilon} \cap B_{r} \\
\left(1-\frac{1}{M}\right) b(y) J(|y|) w_{\epsilon}
\end{array} \text { for } \quad y \in B_{R} \backslash \bar{B}_{r}\right.
$$

It is clear that $f \in L^{\infty}\left(\Omega_{\epsilon}^{R}\right)$, in fact $\|f\|_{L^{\infty}\left(\Omega_{\epsilon}^{R}\right)} \leq(1-1 / M) r^{-(2+N)}$ by using that $w_{\epsilon}(y) \leq C r^{\sigma(p)-N}$ for $|y| \geq r$, when $p<N /(N-2)$, and $w_{\epsilon}(y) \leq C r^{2-N}$ for $|y| \geq r$ when $p>N /(N-2)$. A similar bound is obtained for $p=N /(N-2)$. Then we transform (4.7)-(4.8) in the system

$$
\begin{aligned}
-\Delta J \tilde{w} & =P z_{\epsilon} \text { in } \Omega_{\epsilon}^{R} \\
-\Delta \tilde{z} & =Q J w_{\epsilon}+f \text { in } \Omega_{\epsilon}^{R}
\end{aligned}
$$

We define $\eta_{2}(y)=\chi_{w_{\epsilon} \leq 2 \tilde{w}}(y)$ and $\eta_{1}(y)=\chi_{z_{\epsilon} \leq 2 \tilde{z}}(y)$ for $y \in \Omega_{\epsilon}^{R}$, we find

$$
\begin{aligned}
-\Delta J \tilde{w} & \leq 2 \eta_{1} P \tilde{z}+f_{1} \quad \text { in } \quad \Omega_{\epsilon}^{R} \\
-\Delta \tilde{z} & \leq 2 \eta_{2} Q J \tilde{w}+f_{2} \quad \text { in } \quad \Omega_{\epsilon}^{R}
\end{aligned}
$$

Where $f_{1}=\left(1-\eta_{1}\right) P z_{\epsilon}=\chi_{z_{\epsilon} \leq 2 z_{0}} P z_{\epsilon} \leq 2 P z_{0}$ and $f_{2}=f+\left(1-\eta_{2}\right) Q J w_{\epsilon}$ where $\left(1-\eta_{2}\right) Q J w_{\epsilon} \leq 2 Q J w_{0}$. We write the system in the form

$$
\begin{align*}
-\Delta J \tilde{w} & \leq 2 \eta_{1} P|y|^{\gamma}|y|^{-\gamma} \tilde{z}+f_{1} \quad \text { in } \quad \Omega_{\epsilon}^{R}  \tag{4.10}\\
-|y|^{-\gamma} \Delta \tilde{z} & \leq 2 \eta_{2} Q|y|^{-\gamma} J \tilde{w}+f_{2}|y|^{-\gamma} \quad \text { in } \Omega_{\epsilon}^{R}  \tag{4.11}\\
\tilde{w} & =\tilde{z}=0 \quad \text { on } \quad \partial \Omega_{\epsilon}^{R} . \tag{4.12}
\end{align*}
$$

Let $u(y) \mapsto 2 \eta_{2} Q|y|^{-\gamma} u(y)$ and $u(y) \mapsto 2 \eta_{1} P|y|^{\gamma} u(y)$ be the multiplication operators $\mathcal{P}$ and $\mathcal{Q}$ respectively. Note that a multiplication operator $\mathcal{C}$ with corresponding function $c(y) \in L^{s}\left(\Omega_{\epsilon}^{R}\right)$ is bounded from $L^{s_{1}}\left(\Omega_{\epsilon}^{R}\right)$ to $L^{s_{2}}\left(\Omega_{\epsilon}^{R}\right)$ with $1 / s_{2}=1 / s_{1}+1 / s$.

Formally we define $-L$ the operator as $u(y) \mapsto-|y|^{-\gamma} \Delta\left(|y|^{\gamma} u(y)\right)$. More precisely, in the appendix, we define $(-\Delta)^{-1}$ and $(-L)^{-1}$, which by the Hardy-LittlewoodSobolev inequality are bounded, independently of $\epsilon$, from $L^{m_{1}}\left(\Omega_{\epsilon}^{R}\right)$ to $L^{m_{2}}\left(\Omega_{\epsilon}^{R}\right)$ with $1 / m_{1}=1 / m_{2}+2 / N$. Note that the image of these operators is a function with zero-Dirichlet boundary condition, so they are positive. Then we can write

$$
J \tilde{w} \leq(-\Delta)^{-1} \mathcal{P}(-L)^{-1}\left(\mathcal{Q}(J \tilde{w})+|y|^{-\gamma} f_{2}\right)+(-\Delta)^{-1} f_{1} .
$$

Denoting by $K=(-\Delta)^{-1} \mathcal{P}(-L)^{-1} \mathcal{Q}$ and $h=K|y|^{-\gamma} f_{2}+(-\Delta)^{-1} f_{1}$ we have

$$
(I-K) J \tilde{w} \leq h
$$

The proof is complete finding $m$ large enough such that $h \in L^{m}\left(\Omega_{\epsilon}^{R}\right)$ and $(I-K)$ is invertible from $L^{m}\left(\Omega_{\epsilon}^{R}\right)$ to $L^{m}\left(\Omega_{\epsilon}^{R}\right)$.

We can estimate $Q(y)|y|^{-\gamma}$ in $L^{\frac{q+1}{q-1}}\left(\Omega_{\epsilon}^{R}\right)$, for $\gamma=2 \sigma(p) /(p+1) \geq 0$, and note that $\gamma=-\sigma(q) /(q+1)$ using the Sobolev Hyperbola. Since $v_{\epsilon, \mu} \rightarrow V$ in $L^{q+1}\left(\mathbb{R}^{N}\right)$, we
have

$$
\int_{\Omega_{\epsilon}^{*}}\left[J(|y|) w_{\epsilon}(y)-V\left(y /|y|^{2}\right)|y|^{2-N}\right]^{q+1}|y|^{-\sigma(q)} d y \rightarrow 0 \quad \text { as } \quad \epsilon \rightarrow 0
$$

Therefore for any $\lambda$, we can take $r$ small such that

$$
\int_{\Omega_{\epsilon}^{r}}\left[J w_{\epsilon}\right]^{(q+1) \frac{q_{\epsilon}-1}{q-1}}(y)|y|^{-\sigma(q)} d y \leq \int_{\Omega_{\epsilon}^{r}}\left[J w_{\epsilon}\right]^{(q+1)}(y)|y|^{-\sigma(q)} d y \leq \frac{\lambda}{2 C(\delta)}
$$

and $M$ large such that for all $\epsilon \leq \epsilon_{0}$ we have

$$
\begin{align*}
\int_{\Omega_{\epsilon}^{R}}\left[Q(s)|y|^{-\gamma}\right]^{\frac{q+1}{q-1}} d y \leq & C(\delta) \int_{\Omega_{\epsilon}^{r}}\left[J w_{\epsilon}\right]^{(q+1) \frac{q_{\epsilon}-1}{q-1}}|y|^{-\sigma(q)} d y \\
& +\frac{C(\delta)}{M^{\frac{q+1}{q-1}}} \int_{B_{R} \backslash B_{r}}\left[J w_{\epsilon}\right]^{(q+1)^{\frac{q_{\epsilon}-1}{q-1}}|y|^{-\sigma(q)} d y \leq \lambda} \tag{4.13}
\end{align*}
$$

where we have used $b(y) \leq C(\delta)\left[J w_{\epsilon}\right]^{q_{\epsilon}-1}$ with $\delta$ given by Lemma 2.2,
Now we show that $K$ is bounded from $L^{m}\left(\Omega_{\epsilon}^{R}\right)$ to $L^{m}\left(\Omega_{\epsilon}^{R}\right)$.

$$
\begin{aligned}
\|K J \tilde{w}\|_{L^{m}\left(\Omega_{\epsilon}^{R}\right)} & \leq C_{1}\left\|\mathcal{P}(-L)^{-1} \mathcal{Q} J \tilde{w}\right\|_{L^{r}\left(\Omega_{e}^{R}\right)} \\
& \leq C_{1}\left\||y|^{\gamma} 2 \eta_{1} P\right\|_{L^{\frac{p+1}{p-1}\left(\Omega_{e}^{R}\right)}}\left\|(-L)^{-1} \mathcal{Q} J \tilde{w}\right\|_{L^{r^{\prime}\left(\Omega_{e}^{R}\right)}} \\
& \leq C_{1}\left\||y|^{\gamma} 2 \eta_{1} P\right\|_{L^{\frac{p+1}{p-1}\left(\Omega_{\epsilon}^{R}\right)}} C_{2}\|\mathcal{Q} J \tilde{w}\|_{L^{s^{\prime}}\left(\Omega_{e}^{R}\right)} \\
& \leq C_{1} C_{2}\left\||y|^{\gamma} 2 \eta_{1} P\right\|_{L^{\frac{p+1}{p-1}\left(\Omega_{e}^{R}\right)}}\left\|\left.y\right|^{-\gamma} 2 \eta_{2} Q\right\|_{L^{\frac{q+1}{q-1}\left(\Omega_{e}^{R}\right)}}\|J \tilde{w}\|_{L^{m^{\prime}}\left(\Omega_{\epsilon}^{R}\right)} \\
& \leq \bar{C}\left\||y|^{\gamma} P\right\|_{L^{\frac{p+1}{p-1}\left(\Omega_{\epsilon}^{R}\right)}}\left\||y|^{-\gamma} Q\right\|_{L^{\frac{q+1}{q-1}\left(\Omega_{\epsilon}^{R}\right)}}\|J \tilde{w}\|_{L^{m^{\prime}}\left(\Omega_{\epsilon}^{R}\right)}
\end{aligned}
$$

with $\frac{1}{r}=\frac{1}{m}+\frac{2}{N}$, so $r^{\prime}>1$ implies $m>N /(N-2) \cdot \frac{1}{r}=\frac{p-1}{p+1}+\frac{1}{r^{\prime}}$ and $\frac{1}{s^{\prime}}=\frac{1}{r^{\prime}}+\frac{2}{N}$, so condition b) in (5.1) implies $N-2+N / m>2 N /(p+1)$ and $s^{\prime}>1$ implies $m>(q+1) / 2$ so a) in (5.1) holds since $\gamma>0$ and $\frac{1}{s^{\prime}}=\frac{q-1}{q+1}+\frac{1}{m^{\prime}}$. Since

$$
\frac{q-1}{q+1}+\frac{p-1}{p+1}=\frac{4}{N}, \quad \text { we have } \quad m^{\prime}=m
$$

By

$$
\int_{\Omega_{\epsilon}^{*}}\left[z_{\epsilon}(y)-U\left(y /|y|^{2}\right)|y|^{2-N}\right]^{p+1}|y|^{-\sigma(p)} d y \rightarrow 0 \quad \text { as } \quad \epsilon \rightarrow 0
$$

we deduce that $\left\||y|^{\gamma-\sigma(p)} z_{\epsilon}^{p-1}\right\|_{L^{\frac{p+1}{p-1}\left(\Omega_{\epsilon}^{R}\right)}}=\left\||y|^{\gamma} P\right\|_{L^{\frac{p+1}{p-1}\left(\Omega_{\epsilon}^{R}\right)}} \leq C\left(\epsilon_{0}\right)$ with $C\left(\epsilon_{0}\right)>0$ and for all $\epsilon \in\left(0, \epsilon_{0}\right)$. Since $\lambda$ in (4.13) can be arbitrarely small then the norm of $K$ is small and so $I-K: L^{m}\left(\Omega_{\epsilon}^{R}\right) \rightarrow L^{m}\left(\Omega_{\epsilon}^{R}\right)$ invertible for $m$ large. We have that

$$
\left\||y|^{-\gamma} f_{2}\right\|_{L^{m}\left(\Omega_{\epsilon}^{R}\right)} \leq r^{-\gamma}\left\|f_{2}\right\|_{L^{\infty}\left(\Omega_{r}^{R}\right)}\left(\operatorname{meas}\left(\Omega_{r}^{R}\right)\right)^{1 / m}
$$

is bounded, since $f_{2}$ is zero outside $\Omega_{r}^{R}$ and

$$
\left\|\Delta^{-1} f_{1}\right\|_{L^{m}\left(\Omega_{\epsilon}^{R}\right)} \leq C_{1}\left\|f_{2}\right\|_{L^{r}\left(\Omega_{\epsilon}^{R}\right)} \leq\left\|f_{1}\right\|_{L^{\infty}\left(\Omega_{r}^{R}\right)}\left(\operatorname{meas}\left(\Omega_{\mu}^{R}\right)\right)^{1 / r} \leq C\left(z_{0}\right)\left(\operatorname{meas}\left(B_{R}\right)\right)^{1 / r}
$$

This implies $\|J w\|_{L^{m}\left(\Omega_{e}^{R}\right)} \leq M$ for every $m$ large, and consequently for every $m \geq 1$. (Use the $w_{0}$ to get that $\left.\left\|J w_{\epsilon}\right\|_{L^{m}\left(\Omega_{\epsilon}^{R}\right)} \leq M\right)$. Now we have that

$$
-\Delta \tilde{z}=b(y) J w_{\epsilon}=|y|^{-\sigma(q)+\left(q-q_{\epsilon}\right)(N-2)}\left[J w_{\epsilon}\right]^{q_{\epsilon}} .
$$

Since $\sigma(q) \leq 0$, if we take $m$ large such that $m q_{\epsilon}>N / 2$ then

$$
\begin{equation*}
\|\tilde{z}\|_{L^{\infty}\left(\Omega_{\epsilon}^{R}\right)} \leq \tilde{M} \quad \text { and therefore } \quad\left\|z_{\epsilon}\right\|_{L^{\infty}\left(\Omega_{\epsilon}^{R}\right)} \leq M \tag{4.14}
\end{equation*}
$$

for some $M$ independent of $\epsilon$. We study now each case of $J$ separately. We have

$$
\begin{equation*}
-\Delta J w_{\epsilon}=|y|^{-\sigma(p)} z_{\epsilon}^{p} \quad \text { in } \quad \Omega_{\epsilon}^{*} \tag{4.15}
\end{equation*}
$$

a) In the case $J=1$, since $\sigma(p)<2$, using (4.14), we have $-\Delta \tilde{w}_{\epsilon} \in L^{q}(\Omega)$ for any $q \in(N / 2, N / \sigma(p))$. By regularity, we get

$$
\left\|w_{\epsilon}\right\|_{L^{\infty}\left(\Omega_{\epsilon}^{R}\right)} \leq M
$$

b) For $J(|y|)=-\log (|y| / \bar{R})>\log (\bar{R} / R)$, we have

$$
-\Delta \tilde{w}-\frac{\nabla J}{J} \nabla \tilde{w}-\frac{\Delta J}{J} \tilde{w}=\frac{1}{J|y|^{2}} z_{\epsilon}^{p} \quad \text { in } \quad \Omega_{\epsilon}^{R}
$$

or equivalently

$$
-\Delta \tilde{w}+\frac{1}{J|y|^{2}}(y, \nabla \tilde{w})+\frac{1}{J|y|^{2}}(N-2) \tilde{w}=\frac{1}{J|y|^{2}} z_{\epsilon}^{p} \quad \text { in } \quad \Omega_{\epsilon}^{R}
$$

Using (4.14), we can take $u=\tilde{w}-M$ with $M=\sup _{\epsilon>0} \sup _{y \in \Omega_{\epsilon}^{R}} z_{\epsilon}^{p}(y) /(N-2)$, and we get

$$
-J|y|^{2} \Delta u+(y, \nabla u)+(N-2) u \leq 0 \quad \text { in } \quad \Omega_{\epsilon}^{R} .
$$

Since $u=-M<0$ on the boundary, $u \leq 0$ in $\Omega_{\epsilon}^{R}$. This gives $w_{\epsilon} \leq M$ in $\Omega_{\epsilon}^{R}$.
For the remaining case, $p<N /(N-2)$ we have

$$
-\Delta \tilde{w}-\frac{\nabla J}{J} \nabla \tilde{w}-\frac{\Delta J}{J} \tilde{w}=\frac{1}{|y|^{2}} z_{\epsilon}^{p} \quad \text { in } \quad \Omega_{\epsilon}^{R} .
$$

As before, defining $u=\tilde{w}-M$ with $M=\sup _{\epsilon>0} \sup _{y \in \Omega_{\epsilon}^{R}} z_{\epsilon}^{p} /[(\sigma(p)-2)(N-\sigma(p))]$ then

$$
-|y|^{2} \Delta u-(2-\sigma(p))(y, \nabla u)-(2-\sigma(p))(N-\sigma(p)) u \leq 0 \quad \text { in } \quad \Omega_{\epsilon}^{R}
$$

Since $u=-M<0$ on the boundary, $u \leq 0$ in $\Omega_{\epsilon}^{R}$. This implies $w_{\epsilon} \leq M$ in $\Omega_{\epsilon}^{R}$.

## 5. Appendix

Let $N>2$. Let $h$ and $v$ be a function in $L^{s^{\prime}}\left(\Omega_{\epsilon}^{R}\right)$. Given the Green's function $G$ solution of $-\Delta G(x, \cdot)=\delta_{x}$ in $\Omega_{\epsilon}^{R}, G(x, \cdot)=0$ on $\partial \Omega_{\epsilon}^{R}$, we define

$$
(-\Delta)^{-1} h(\xi)=\int_{\Omega_{\epsilon}^{R}} G(x, \xi) h(x) d x \quad \xi \in \Omega_{\epsilon}^{R}
$$

and

$$
(-L)^{-1} v(\xi)=|\xi|^{-\gamma} \int_{\Omega_{\epsilon}^{R}} G(x, \xi)|x|^{\gamma} v(x) d x \quad \xi \in \Omega_{\epsilon}^{R}
$$

Note that $G$ is positive, so both operators are positive. We know that $(-\Delta)^{-1}$ is bounded, independently of $\epsilon$, from $L^{s^{\prime}}\left(\Omega_{\epsilon}^{R}\right)$ to $L^{r^{\prime}}\left(\Omega_{\epsilon}^{R}\right)$ with $1 / r^{\prime}=1 / s^{\prime}-2 / N$. Next we prove the same result for $(-L)^{-1}$. By the weighted Hardy-Littlewood-Sobolev inequality [5] (17), for $|\xi|^{-\gamma} f \in L^{s^{\prime}}\left(\Omega_{\epsilon}^{R}\right)$, we have that

$$
\left\|\xi^{-\gamma}(-\Delta)^{-1} f\right\|_{L^{r^{\prime}}\left(\Omega_{e}^{R}\right)} \leq\left. 2\| \| \xi\right|^{-\gamma} \int_{\Omega_{e}^{R}} \frac{C}{|x-\xi|^{N-2}} f(x) d x\left\|_{L^{r^{\prime}\left(\Omega_{e}^{R}\right)}} \leq C\right\|\left\|\left.\xi\right|^{-\gamma} f\right\|_{L^{s^{\prime}\left(\Omega_{e}^{R}\right)}}
$$

for $1<s^{\prime}<r^{\prime}<\infty$, with $1 / r^{\prime}=1 / s^{\prime}-2 / N$ and

$$
\begin{equation*}
\text { a) } \quad-\gamma<N\left(1-1 / s^{\prime}\right)=N-2-N / r^{\prime} \quad \text { and } \quad \text { b) } \quad \gamma<N / r^{\prime} \text {. } \tag{5.1}
\end{equation*}
$$

In other words, for any $v \in L^{s^{\prime}}\left(\Omega_{\epsilon}^{R}\right)$, we have

$$
\begin{align*}
\left\|(-L)^{-1} v\right\|_{L^{r^{\prime}}\left(\Omega_{\epsilon}^{R}\right)} & =\left\||\xi|^{-\gamma}(-\Delta)^{-1}|x|^{\gamma} v\right\|_{L^{r^{\prime}}\left(\Omega_{e}^{R}\right)} \\
& \leq 2\left\||\xi|^{-\gamma} \int_{\Omega_{e}^{R}} \frac{C}{|x-\xi|^{N-2}}|x|^{\gamma} v(x) d x\right\|_{L^{r^{\prime}}\left(\Omega_{\epsilon}^{R}\right)} \\
& \leq C\|v\|_{L^{s^{\prime}}\left(\Omega_{\epsilon}^{R}\right)} . \tag{5.2}
\end{align*}
$$

Lemma 5.1. Let u solve

$$
\left\{\begin{array}{l}
-\Delta u=f \quad \text { in } \quad \Omega \subset \mathbb{R}^{N} \\
u=0 \quad \text { on } \quad \partial \Omega
\end{array}\right.
$$

Let $\omega$ be a neighborhood of $\partial \Omega$. Then

$$
\|u\|_{W^{1, q}(\Omega)}+\|\nabla u\|_{C^{0, \alpha}\left(\omega^{\prime}\right)} \leq C\left(\|f\|_{L^{1}(\Omega)}+\|f\|_{L^{\infty}(\omega)}\right)
$$

for $q<N /(N-1), \alpha \in(0,1)$ and $\omega^{\prime} \subset \omega$ is a strict subdomain of $\omega$.
